## Chapter 1

# FrameworkBundle Configuration ("framework")

The FrameworkBundle defines the main framework configuration, from sessions and translations to forms, validation, routing and more. All these options are configured under the `framework` key in your application configuration.

*Listing 1-1*

```
1 # displays the default config values defined by Symfony
2 $ php bin/console config:dump framework
3
4 # displays the actual config values used by your application
5 $ php bin/console debug:config framework
```

When using XML, you must use the `http://symfony.com/schema/dic/symfony` namespace and the related XSD schema is available at: `http://symfony.com/schema/dic/symfony/symfony-1.0.xsd`

## Configuration

- lock

## secret

### type: string required

This is a string that should be unique to your application and it's commonly used to add more entropy to security related operations. Its value should be a series of characters, numbers and symbols chosen randomly and the recommended length is around 32 characters.

In practice, Symfony uses this value for encrypting the cookies used in the *remember me functionality* and for creating signed URIs when using ESI (Edge Side Includes).

This option becomes the service container parameter named `kernel.secret`, which you can use whenever the application needs an immutable random string to add more entropy.

As with any other security-related parameter, it is a good practice to change this value from time to time. However, keep in mind that changing this value will invalidate all signed URIs and Remember Me cookies. That's why, after changing this value, you should regenerate the application cache and log out all the application users.

## http\_method\_override

### type: boolean default: true

This determines whether the `_method` request parameter is used as the intended HTTP method on POST requests. If enabled, the `Request::enableHttpMethodParameterOverride`<sup>1</sup> method gets called automatically. It becomes the service container parameter named `kernel.http_method_override`.

*For more information, see [How to Change the Action and Method of a Form](#).*

---

1. [https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method\\_enableHttpMethodParameterOverride](https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method_enableHttpMethodParameterOverride)

If you're using the `HttpCache Reverse Proxy` with this option, the kernel will ignore the `_method` parameter, which could lead to errors.

To fix this, invoke the `enableHttpMethodParameterOverride()` method before creating the `Request` object:

Listing 1-2

```
1 // public/index.php
2
3 // ...
4 $kernel = new CacheKernel($kernel);
5
6 Request::enableHttpMethodParameterOverride(); // <-- add this line
7 $request = Request::createFromGlobals();
8 // ...
```

## trusted\_proxies

The `trusted_proxies` option was removed in Symfony 3.3. See *How to Configure Symfony to Work behind a Load Balancer or a Reverse Proxy*.

## ide

**type:** string **default:** null

Symfony turns file paths seen in variable dumps and exception messages into links that open those files right inside your browser. If you prefer to open those files in your favorite IDE or text editor, set this option to any of the following values: `phpstorm`, `sublime`, `textmate`, `macvim` and `emacs`.

The `phpstorm` option is supported natively by PhpStorm on MacOS, Windows requires *PhpStormProtocol*<sup>2</sup> and Linux requires *phpstorm-url-handler*<sup>3</sup>.

If you use another editor, the expected configuration value is a URL template that contains an `%f` placeholder where the file path is expected and `%l` placeholder for the line number (percentage signs (%) must be escaped by doubling them to prevent Symfony from interpreting them as container parameters).

Listing 1-3

```
1 # config/packages/framework.yaml
2 framework:
3     ide: 'myide://open?url=file://%%f&line=%l'
```

Since every developer uses a different IDE, the recommended way to enable this feature is to configure it on a system level. This can be done by setting the `xdebug.file_link_format` option in your `php.ini` configuration file. The format to use is the same as for the `framework.ide` option, but without the need to escape the percent signs (%) by doubling them.

If both `framework.ide` and `xdebug.file_link_format` are defined, Symfony uses the value of the `xdebug.file_link_format` option.

Setting the `xdebug.file_link_format` ini option works even if the Xdebug extension is not enabled.

2. <https://github.com/aik099/PhpStormProtocol>

3. <https://github.com/sanduhrs/phpstorm-url-handler>

When running your app in a container or in a virtual machine, you can tell Symfony to map files from the guest to the host by changing their prefix. This map should be specified at the end of the URL template, using `&` and `>` as guest-to-host separators:

```
Listing 1-4 // /path/to/guest/.../file will be opened
// as /path/to/host/.../file on the host
// and /foo/.../file as /bar/.../file also
'myide://%f:%l&/path/to/guest/>/path/to/host/&/foo/>/bar/&...'
```

## test

**type:** boolean

If this configuration setting is present (and not `false`), then the services related to testing your application (e.g. `test.client`) are loaded. This setting should be present in your `test` environment (usually via `config/packages/test/framework.yaml`).

*For more information, see [Testing](#).*

## default\_locale

**type:** string **default:** en

The default locale is used if no `_locale` routing parameter has been set. It is available with the `Request::getDefaultLocale`<sup>4</sup> method.

*You can read more information about the default locale in [Setting a Default Locale](#).*

## trusted\_hosts

**type:** array | string **default:** array()

A lot of different attacks have been discovered relying on inconsistencies in handling the `Host` header by various software (web servers, reverse proxies, web frameworks, etc.). Basically, every time the framework is generating an absolute URL (when sending an email to reset a password for instance), the host might have been manipulated by an attacker.

*You can read "[HTTP Host header attacks](#)"<sup>5</sup> for more information about these kinds of attacks.*

The Symfony `Request::getHost`<sup>6</sup> method might be vulnerable to some of these attacks because it depends on the configuration of your web server. One simple solution to avoid these attacks is to whitelist the hosts that your Symfony application can respond to. That's the purpose of this `trusted_hosts` option. If the incoming request's hostname doesn't match one in this list, the application won't respond and the user will receive a 400 response.

```
Listing 1-5 1 # config/packages/framework.yaml
2 framework:
3     trusted_hosts: ['example.com', 'example.org']
```

Hosts can also be configured using regular expressions (e.g. `^(.+\.)?example.com$`), which make it easier to respond to any subdomain.

4. [https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method\\_getDefaultLocale](https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method_getDefaultLocale)

5. <http://www.skeletonscribe.net/2013/05/practical-http-host-header-attacks.html>

6. [https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method\\_getHost](https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method_getHost)

In addition, you can also set the trusted hosts in the front controller using the `Request::setTrustedHosts()` method:

Listing 1-6 

```
// public/index.php
Request::setTrustedHosts(array('^(\.+\.)?example.com$', '^(\.+\.)?example.org$'));
```

The default value for this option is an empty array, meaning that the application can respond to any given host.

*Read more about this in the Security Advisory Blog post<sup>7</sup>.*

## form

### enabled

**type:** boolean **default:** true or false depending on your installation

Whether to enable the form services or not in the service container. If you don't use forms, setting this to **false** may increase your application's performance because less services will be loaded into the container.

This option will automatically be set to **true** when one of the child settings is configured.

This will automatically enable the validation.

*For more details, see Forms.*

## csrf\_protection

*For more information about CSRF protection, see How to Implement CSRF Protection.*

### enabled

**type:** boolean **default:** true or false depending on your installation

This option can be used to disable CSRF protection on *all* forms. But you can also disable CSRF protection on individual forms.

If you're using forms, but want to avoid starting your session (e.g. using forms in an API-only website), `csrf_protection` will need to be set to **false**.

## esi

*You can read more about Edge Side Includes (ESI) in Working with Edge Side Includes.*

### enabled

**type:** boolean **default:** false

Whether to enable the edge side includes support in the framework.

---

7. <https://symfony.com/blog/security-releases-symfony-2-0-24-2-1-12-2-2-5-and-2-3-3-released#cve-2013-4752-request-gethost-poisoning>

You can also set `esi` to `true` to enable it:

```
Listing 1-7 1 # config/packages/framework.yaml
           2 framework:
           3     esi: true
```

## fragments

*Learn more about fragments in the HTTP Cache article.*

### enabled

**type:** boolean **default:** false

Whether to enable the fragment listener or not. The fragment listener is used to render ESI fragments independently of the rest of the page.

This setting is automatically set to `true` when one of the child settings is configured.

### path

**type:** string **default:** `'/_fragment'`

The path prefix for fragments. The fragment listener will only be executed when the request starts with this path.

## profiler

### enabled

**type:** boolean **default:** false

The profiler can be enabled by setting this option to `true`. When you install it using Symfony Flex, the profiler is enabled in the `dev` and `test` environments.

The profiler works independently from the Web Developer Toolbar, see the *WebProfilerBundle configuration* on how to disable/enable the toolbar.

### collect

**type:** boolean **default:** true

This option configures the way the profiler behaves when it is enabled. If set to `true`, the profiler collects data for all requests. If you want to only collect information on-demand, you can set the `collect` flag to `false` and activate the data collectors manually:

```
Listing 1-8 $profiler->enable();
```

### only\_exceptions

**type:** boolean **default:** false

When this is set to `true`, the profiler will only be enabled when an exception is thrown during the handling of the request.

only\_master\_requests

**type:** boolean **default:** false

When this is set to **true**, the profiler will only be enabled on the master requests (and not on the subrequests).

dsn

**type:** string **default:** 'file:%kernel.cache\_dir%/profiler'

The DSN where to store the profiling information.

*See Switching the Profiler Storage for more information about the profiler storage.*

request

formats

**type:** array **default:** []

This setting is used to associate additional request formats (e.g. **html**) to one or more mime types (e.g. **text/html**), which will allow you to use the format & mime types to call *Request::getFormat(\$mimeType)*<sup>8</sup> or *Request::getMimeType(\$format)*<sup>9</sup>.

In practice, this is important because Symfony uses it to automatically set the **Content-Type** header on the **Response** (if you don't explicitly set one). If you pass an array of mime types, the first will be used for the header.

To configure a **jsonp** format:

Listing 1-9

```
1 # config/packages/framework.yaml
2 framework:
3     request:
4         formats:
5             jsonp: 'application/javascript'
```

router

resource

**type:** string **required**

The path the main routing resource (e.g. a YAML file) that contains the routes and imports the router should load.

type

**type:** string

The type of the resource to hint the loaders about the format. This isn't needed when you use the default routers with the expected file extensions (**.xml**, **.yaml** or **.php**).

http\_port

**type:** integer **default:** 80

---

8. [https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method\\_getFormat](https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method_getFormat)

9. [https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method\\_getMimeType](https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Request.html#method_getMimeType)

The port for normal http requests (this is used when matching the scheme).

`https_port`

**type:** integer **default:** 443

The port for https requests (this is used when matching the scheme).

`strict_requirements`

**type:** mixed **default:** true

Determines the routing generator behaviour. When generating a route that has specific *requirements*, the generator can behave differently in case the used parameters do not meet these requirements.

The value can be one of:

**true**

Throw an exception when the requirements are not met;

**false**

Disable exceptions when the requirements are not met and return `null` instead;

**null**

Disable checking the requirements (thus, match the route even when the requirements don't match).

**true** is recommended in the development environment, while **false** or **null** might be preferred in production.

`session`

`storage_id`

**type:** string **default:** 'session.storage.native'

The service id used for session storage. The `session.storage` service alias will be set to this service id. This class has to implement *SessionStorageInterface*<sup>10</sup>.

`handler_id`

**type:** string **default:** 'session.handler.native\_file'

The service id used for session storage. The `session.handler` service alias will be set to this service id.

You can also set it to `null`, to default to the handler of your PHP installation.

*You can see an example of the usage of this in [How to Use PdoSessionHandler to Store Sessions in the Database](#).*

`name`

**type:** string **default:** null

This specifies the name of the session cookie. By default it will use the cookie name which is defined in the `php.ini` with the `session.name` directive.

---

10. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Session/Storage/SessionStorageInterface.html>

`cookie_lifetime`

**type: integer default: null**

This determines the lifetime of the session - in seconds. The default value - `null` - means that the `session.cookie_lifetime` value from `php.ini` will be used. Setting this value to `0` means the cookie is valid for the length of the browser session.

`cookie_path`

**type: string default: /**

This determines the path to set in the session cookie. By default it will use `/`.

`cookie_domain`

**type: string default: ''**

This determines the domain to set in the session cookie. By default it's blank, meaning the host name of the server which generated the cookie according to the cookie specification.

`cookie_secure`

**type: boolean default: false**

This determines whether cookies should only be sent over secure connections.

`cookie_httponly`

**type: boolean default: true**

This determines whether cookies should only be accessible through the HTTP protocol. This means that the cookie won't be accessible by scripting languages, such as JavaScript. This setting can effectively help to reduce identity theft through XSS attacks.

`gc_divisor`

**type: integer default: 100**

See `gc_probability`.

`gc_probability`

**type: integer default: 1**

This defines the probability that the garbage collector (GC) process is started on every session initialization. The probability is calculated by using `gc_probability / gc_divisor`, e.g. `1/100` means there is a 1% chance that the GC process will start on each request.

`gc_maxlifetime`

**type: integer default: 1440**

This determines the number of seconds after which data will be seen as "garbage" and potentially cleaned up. Garbage collection may occur during session start and depends on `gc_divisor` and `gc_probability`.

`save_path`

**type: string default: %kernel.cache\_dir%/sessions**

This determines the argument to be passed to the save handler. If you choose the default file handler, this is the path where the session files are created. For more information, see *Configuring the Directory where Session Files are Saved*.

You can also set this value to the `save_path` of your `php.ini` by setting the value to `null`:

```
Listing 1-10 1 # config/packages/framework.yaml
2 framework:
3     session:
4         save_path: ~
```

## metadata\_update\_threshold

**type:** integer **default:** 0

This is how many seconds to wait between updating/writing the session metadata. This can be useful if, for some reason, you want to limit the frequency at which the session persists.

Starting in Symfony 3.4, session data is *only* written when the session data has changed. Previously, you needed to set this option to avoid that behavior.

## assets

### base\_path

**type:** string

This option allows you to define a base path to be used for assets:

```
Listing 1-11 1 # config/packages/framework.yaml
2 framework:
3     # ...
4     assets:
5         base_path: '/images'
```

### base\_urls

**type:** array

This option allows you to define base URLs to be used for assets. If multiple base URLs are provided, Symfony will select one from the collection each time it generates an asset's path:

```
Listing 1-12 1 # config/packages/framework.yaml
2 framework:
3     # ...
4     assets:
5         base_urls:
6             - 'http://cdn.example.com/'
```

## packages

You can group assets into packages, to specify different base URLs for them:

```
Listing 1-13 1 # config/packages/framework.yaml
2 framework:
3     # ...
4     assets:
5         packages:
6             avatars:
7                 base_urls: 'http://static_cdn.example.com/avatars'
```

Now you can use the **avatars** package in your templates:

```
Listing 1-14 1 
```

Each package can configure the following options:

- `base_path`
- `base_urls`
- `version_strategy`
- `version`
- `version_format`
- `json_manifest_path`

## version

### type: string

This option is used to *bust* the cache on assets by globally adding a query parameter to all rendered asset paths (e.g. `/images/logo.png?v2`). This applies only to assets rendered via the Twig `asset()` function (or PHP equivalent) as well as assets rendered with Assetic.

For example, suppose you have the following:

```
Listing 1-15 1 
```

By default, this will render a path to your image such as `/images/logo.png`. Now, activate the **version** option:

```
Listing 1-16 1 # config/packages/framework.yaml
2 framework:
3     # ...
4     assets:
5         version: 'v2'
```

Now, the same asset will be rendered as `/images/logo.png?v2`. If you use this feature, you **must** manually increment the **version** value before each deployment so that the query parameters change.

You can also control how the query string works via the `version_format` option.

This parameter cannot be set at the same time as **version\_strategy** or **json\_manifest\_path**.

As with all settings, you can use a parameter as value for the **version**. This makes it easier to increment the cache on each deployment.

## version\_format

### type: string default: `%%s?%%s`

This specifies a *sprintf*<sup>11</sup> pattern that will be used with the **version** option to construct an asset's path. By default, the pattern adds the asset's version as a query string. For example, if **version\_format** is set to `%%s?version=%%s` and **version** is set to `5`, the asset's path would be `/images/logo.png?version=5`.

---

11. <https://secure.php.net/manual/en/function.sprintf.php>

All percentage signs (%) in the format string must be doubled to escape the character. Without escaping, values might inadvertently be interpreted as Service Parameters.

Some CDN's do not support cache-busting via query strings, so injecting the version into the actual file path is necessary. Thankfully, `version_format` is not limited to producing versioned query strings.

The pattern receives the asset's original path and version as its first and second parameters, respectively. Since the asset's path is one parameter, you cannot modify it in-place (e.g. `/images/logo-v5.png`); however, you can prefix the asset's path using a pattern of `version-%2$s/%1$s`, which would result in the path `version-5/images/logo.png`.

URL rewrite rules could then be used to disregard the version prefix before serving the asset. Alternatively, you could copy assets to the appropriate version path as part of your deployment process and forget any URL rewriting. The latter option is useful if you would like older asset versions to remain accessible at their original URL.

## version\_strategy

**type:** string **default:** null

The service id of the *asset version strategy* applied to the assets. This option can be set globally for all assets and individually for each asset package:

```
Listing 1-17 1 # config/packages/framework.yaml
2 framework:
3     assets:
4         # this strategy is applied to every asset (including packages)
5         version_strategy: 'app.asset.my_versioning_strategy'
6     packages:
7         foo_package:
8             # this package removes any versioning (its assets won't be versioned)
9             version: ~
10        bar_package:
11            # this package uses its own strategy (the default strategy is ignored)
12            version_strategy: 'app.asset.another_version_strategy'
13        baz_package:
14            # this package inherits the default strategy
15            base_path: '/images'
```

This parameter cannot be set at the same time as `version` or `json_manifest_path`.

## json\_manifest\_path

**type:** string **default:** null

The file path to a `manifest.json` file containing an associative array of asset names and their respective compiled names. A common cache-busting technique using a "manifest" file works by writing out assets with a "hash" appended to their file names (e.g. `main.ae433f1cb.css`) during a front-end compilation routine.

Symfony's Webpack Encore supports outputting hashed assets. Moreover, this can be incorporated into many other workflows, including Webpack and Gulp using *webpack-manifest-plugin*<sup>12</sup> and *gulp-rev*<sup>13</sup>, respectively.

This option can be set globally for all assets and individually for each asset package:

```
Listing 1-18 1 # config/packages/framework.yaml
2 framework:
3   assets:
4     # this manifest is applied to every asset (including packages)
5     json_manifest_path: "%kernel.project_dir%/public/build/manifest.json"
6     packages:
7       foo_package:
8         # this package uses its own manifest (the default file is ignored)
9         json_manifest_path: "%kernel.project_dir%/public/build/a_different_manifest.json"
10      bar_package:
11        # this package uses the global manifest (the default file is used)
12        base_path: '/images'
```

This parameter cannot be set at the same time as **version** or **version\_strategy**. Additionally, this option cannot be nullified at the package scope if a global manifest file is specified.

If you request an asset that is *not found* in the **manifest.json** file, the original - *unmodified* - asset path will be returned.

## templating

### hinclude\_default\_template

**type:** string **default:** null

Sets the content shown during the loading of the fragment or when JavaScript is disabled. This can be either a template name or the content itself.

See *How to Embed Asynchronous Content with hinclude.js* for more information about *hinclude*.

### form

#### resources

**type:** string[] **default:** ['FrameworkBundle:Form']

A list of all resources for form theming in PHP. This setting is not required if you're using the Twig format for your templates, in that case refer to the form article.

Assume you have custom global form themes in **templates/form\_themes/**, you can configure this like:

```
Listing 1-19 1 # config/packages/framework.yaml
2 framework:
3   templating:
4     form:
5       resources:
6         - 'form_themes'
```

The default form templates from **FrameworkBundle:Form** will always be included in the form resources.

12. <https://www.npmjs.com/package/webpack-manifest-plugin>

13. <https://www.npmjs.com/package/gulp-rev>

See *Global Form Theming* for more information.

cache

**type:** string

The path to the cache directory for templates. When this is not set, caching is disabled.

When using Twig templating, the caching is already handled by the TwigBundle and doesn't need to be enabled for the FrameworkBundle.

engines

**type:** string[] / **string required**

The Templating Engine to use. This can either be a string (when only one engine is configured) or an array of engines.

At least one engine is required.

loaders

**type:** string[]

An array (or a string when configuring just one loader) of service ids for templating loaders. Templating loaders are used to find and load templates from a resource (e.g. a filesystem or database). Templating loaders must implement *LoaderInterface*<sup>14</sup>.

translator

enabled

**type:** boolean **default:** true or false depending on your installation

Whether or not to enable the **translator** service in the service container.

fallbacks

**type:** string|array **default:** array('en')

This option is used when the translation key for the current locale wasn't found.

*For more details, see Translations.*

logging

**default:** true when the debug mode is enabled, false otherwise.

When **true**, a log entry is made whenever the translator cannot find a translation for a given key. The logs are made to the **translation** channel and at the **debug** for level for keys where there is a translation in the fallback locale and the **warning** level if there is no translation to use at all.

---

14. <https://api.symfony.com/4.0/Symfony/Component/Templating/Loader/LoaderInterface.html>

paths

**type:** array **default:** []

This option allows to define an array of paths where the component will look for translation files.

property\_access

magic\_call

**type:** boolean **default:** false

When enabled, the `property_accessor` service uses PHP's magic `__call()` method when its `getValue()` method is called.

throw\_exception\_on\_invalid\_index

**type:** boolean **default:** false

When enabled, the `property_accessor` service throws an exception when you try to access an invalid index of an array.

validation

enabled

**type:** boolean **default:** true or false depending on your installation

Whether or not to enable validation support.

This option will automatically be set to **true** when one of the child settings is configured.

cache

**type:** string

The service that is used to persist class metadata in a cache. The service has to implement the *CacheInterface*<sup>15</sup>.

Set this option to `validator.mapping.cache.doctrine.apc` to use the APC cache provide from the Doctrine project.

enable\_annotations

**type:** boolean **default:** false

If this option is enabled, validation constraints can be defined using annotations.

translation\_domain

**type:** string **default:** validators

The translation domain that is used when translating validation constraint error messages.

strict\_email

**type:** Boolean **default:** false

---

15. <https://api.symfony.com/4.0/Symfony/Component/Validator/Mapping/Cache/CacheInterface.html>

If this option is enabled, the *egulias/email-validator*<sup>16</sup> library will be used by the *Email* constraint validator. Otherwise, the validator uses a simple regular expression to validate email addresses.

## mapping

### paths

**type:** array **default:** []

This option allows to define an array of paths with files or directories where the component will look for additional validation files.

## annotations

### cache

**type:** string **default:** 'file'

This option can be one of the following values:

#### file

Use the filesystem to cache annotations

#### none

Disable the caching of annotations

#### a service id

A service id referencing a *Doctrine Cache*<sup>17</sup> implementation

### file\_cache\_dir

**type:** string **default:** '%kernel.cache\_dir%/annotations'

The directory to store cache files for annotations, in case `annotations.cache` is set to 'file'.

## debug

**type:** boolean **default:** %kernel.debug%

Whether to enable debug mode for caching. If enabled, the cache will automatically update when the original file is changed (both with code and annotation changes). For performance reasons, it is recommended to disable debug mode in production, which will happen automatically if you use the default value.

## serializer

### enabled

**type:** boolean **default:** true or false depending on your installation

Whether to enable the `serializer` service or not in the service container.

### enable\_annotations

**type:** boolean **default:** false

If this option is enabled, serialization groups can be defined using annotations.

---

16. <https://github.com/egulias/EmailValidator>

17. <http://docs.doctrine-project.org/projects/doctrine-common/en/latest/reference/caching.html>

For more information, see *Using Serialization Groups Annotations*.

#### name\_converter

**type:** string

The name converter to use. The *CamelCaseToSnakeCaseNameConverter*<sup>18</sup> name converter can be enabled by using the `serializer.name_converter.camel_case_to_snake_case` value.

For more information, see *Converting Property Names when Serializing and Deserializing*.

#### circular\_reference\_handler

**type:** string

The service id that is used as the circular reference handler of the default serializer. The service has to implement the magic `__invoke($object)` method.

For more information, see *Handling Circular References*.

#### mapping

##### paths

**type:** array **default:** [ ]

This option allows to define an array of paths with files or directories where the component will look for additional serialization files.

#### php\_errors

##### log

**type:** boolean **default:** false

Use the application logger instead of the PHP logger for logging PHP errors.

##### throw

**type:** boolean **default:** %kernel.debug%

Throw PHP errors as `\ErrorException` instances. The parameter `debug.error_handler.throw_at` controls the threshold.

#### cache

##### app

**type:** string **default:** cache.adapter.filesystem

The cache adapter used by the `cache.app` service. The FrameworkBundle ships with multiple adapters: `cache.adapter.apcu`, `cache.adapter.doctrine`, `cache.adapter.system`, `cache.adapter.filesystem`, `cache.adapter.psr6`, `cache.adapter.redis` and `cache.adapter.memcached`.

---

18. <https://api.symfony.com/4.0/Symfony/Component/Serializer/NameConverter/CamelCaseToSnakeCaseNameConverter.html>

It might be tough to understand at the beginning, so to avoid confusion remember that all pools perform the same actions but on different medium given the adapter they are based on. Internally, a pool wraps the definition of an adapter.

#### system

**type:** string **default:** `cache.adapter.system`

The cache adapter used by the `cache.system` service. It supports the same adapters available for the `cache.app` service.

#### directory

**type:** string **default:** `%kernel.cache_dir%/pools`

The path to the cache directory used by services inheriting from the `cache.adapter.filesystem` adapter (including `cache.app`).

#### default\_doctrine\_provider

**type:** string

The service name to use as your default Doctrine provider. The provider is available as the `cache.doctrine` service.

#### default\_psr6\_provider

**type:** string

The service name to use as your default PSR-6 provider. It is available as the `cache.psr6` service.

#### default\_redis\_provider

**type:** string **default:** `redis://localhost`

The DSN to use by the Redis provider. The provider is available as the `cache.redis` service.

#### default\_memcached\_provider

**type:** string **default:** `memcached://localhost`

The DSN to use by the Memcached provider. The provider is available as the `cache.memcached` service.

#### pools

**type:** array

A list of cache pools to be created by the framework extension.

*For more information about how pools works, see [cache pools](#).*

#### name

**type:** prototype

Name of the pool you want to create.

Your pool name must differ from `cache.app` or `cache.system`.

adapter

**type:** string **default:** `cache.app`

The name of the adapter to use. You could also use your own implementation.

Your service MUST implement the *CacheItemPoolInterface*<sup>19</sup> interface.

public

**type:** boolean **default:** `false`

Whether your service should be public or not.

default\_lifetime

**type:** integer

Default lifetime of your cache items in seconds.

provider

**type:** string

The service name to use as provider when the specified adapter needs one.

clearer

**type:** string

The cache clearer used to clear your PSR-6 cache.

*For more information, see [Psr6CacheClearer](#)<sup>20</sup>.*

prefix\_seed

**type:** string **default:** `null`

If defined, this value is used as part of the "namespace" generated for the cache item keys. A common practice is to use the unique name of the application (e.g. `symfony.com`) because that prevents naming collisions when deploying multiple applications into the same path (on different servers) that share the same cache backend.

It's also useful when using *blue/green deployment*<sup>21</sup> strategies and more generally, when you need to abstract out the actual deployment directory (for example, when warming caches offline).

lock

**type:** string

The default lock adapter. If not defined, the value is set to `semaphore` when available, or to `flock` otherwise. Store's DSN are also allowed.

```

## Doctrine DBAL Configuration

DoctrineBundle supports all parameters that default Doctrine drivers accept, converted to the XML or YAML naming standards that Symfony enforces. See the Doctrine *DBAL documentation*<sup>1</sup> for more information. The following block shows all possible configuration keys:

Listing 2-2

```
1 doctrine:
2   dbal:
3     dbname:      database
4     host:        localhost
5     port:        1234
6     user:        user
7     password:    secret
8     driver:      pdo_mysql
9     # if the url option is specified, it will override the above config
10    url:          mysql://db_user:db_password@127.0.0.1:3306/db_name
11    # the DBAL driverClass option
12    driver_class: App\DBAL\MyDatabaseDriver
13    # the DBAL driverOptions option
14    options:
15      foo: bar
16    path:          '%kernel.project_dir%/var/data/data.sqlite'
17    memory:        true
18    unix_socket:  /tmp/mysql.sock
19    # the DBAL wrapperClass option
20    wrapper_class: App\DBAL\MyConnectionWrapper
21    charset:       UTF8
22    logging:       '%kernel.debug%'
23    platform_service: App\DBAL\MyDatabasePlatformService
24    server_version: '5.6'
25    mapping_types:
26      enum: string
27    types:
28      custom: App\DBAL\MyCustomType
```

The `server_version` option was added in Doctrine DBAL 2.5, which is used by DoctrineBundle 1.3. The value of this option should match your database server version (use `postgres -V` or `psql -V` command to find your PostgreSQL version and `mysql -V` to get your MySQL version).

If you are running a MariaDB database, you must prefix the `server_version` value with `mariadb-` (e.g. `server_version: mariadb-10.2.12`).

Always wrap the server version number with quotes to parse it as a string instead of a float number. Otherwise, the floating-point representation issues can make your version be considered a different number (e.g. `5.6` will be rounded as `5.5999999999999996447286321199499070644378662109375`).

If you don't define this option and you haven't created your database yet, you may get `PDOException` errors because Doctrine will try to guess the database server version automatically and none is available.

If you want to configure multiple connections in YAML, put them under the `connections` key and give them a unique name:

Listing 2-3

```
1 doctrine:
2   dbal:
3     default_connection: default
4     connections:
5       default:
6         dbname:  Symfony
7         user:    root
```

1. <http://docs.doctrine-project.org/projects/doctrine-dbal/en/latest/reference/configuration.html>

```

8         password:      null
9         host:          localhost
10        server_version: 5.6
11    customer:
12        dbname:        customer
13        user:          root
14        password:      null
15        host:          localhost
16        server_version: 5.7

```

The `database_connection` service always refers to the *default* connection, which is the first one defined or the one configured via the `default_connection` parameter.

Each connection is also accessible via the `doctrine.dbal.[name]_connection` service where `[name]` is the name of the connection.

## Doctrine ORM Configuration

This following configuration example shows all the configuration defaults that the ORM resolves to:

*Listing 2-4*

```

1 doctrine:
2   orm:
3     auto_mapping: true
4     # the standard distribution overrides this to be true in debug, false otherwise
5     auto_generate_proxy_classes: false
6     proxy_namespace: Proxies
7     proxy_dir: '%kernel.cache_dir%/doctrine/orm/Proxies'
8     default_entity_manager: default
9     metadata_cache_driver: array
10    query_cache_driver: array
11    result_cache_driver: array

```

There are lots of other configuration options that you can use to overwrite certain classes, but those are for very advanced use-cases only.

## Shortened Configuration Syntax

When you are only using one entity manager, all config options available can be placed directly under `doctrine.orm` config level.

*Listing 2-5*

```

1 doctrine:
2   orm:
3     # ...
4     query_cache_driver:
5     # ...
6     metadata_cache_driver:
7     # ...
8     result_cache_driver:
9     # ...
10    connection: ~
11    class_metadata_factory_name: Doctrine\ORM\Mapping\ClassMetadataFactory
12    default_repository_class: Doctrine\ORM\EntityRepository
13    auto_mapping: false
14    hydrators:
15    # ...
16    mappings:
17    # ...
18    dql:
19    # ...
20    filters:
21    # ...

```

This shortened version is commonly used in other documentation sections. Keep in mind that you can't use both syntaxes at the same time.

## Caching Drivers

The built-in types of caching drivers are: **array**, **apc**, **apcu**, **memcache**, **memcached**, **redis**, **wincache**, **zenddata** and **xcache**. There is a special type called **service** which lets you define the ID of your own caching service.

The following example shows an overview of the caching configurations:

```
Listing 2-6 1 doctrine:
           2   orm:
           3     auto_mapping: true
           4     # each caching driver type defines its own config options
           5     metadata_cache_driver: apc
           6     result_cache_driver:
           7       type: memcache
           8       host: localhost
           9       port: 11211
          10       instance_class: Memcache
          11     # the 'service' type requires to define the 'id' option too
          12     query_cache_driver:
          13       type: service
          14       id: App\ORM\MyCacheService
```

## Mapping Configuration

Explicit definition of all the mapped entities is the only necessary configuration for the ORM and there are several configuration options that you can control. The following configuration options exist for a mapping:

### type

One of **annotation** (the default value), **xml**, **yml**, **php** or **staticphp**. This specifies which type of metadata type your mapping uses.

### dir

Absolute path to the mapping or entity files (depending on the driver).

### prefix

A common namespace prefix that all entities of this mapping share. This prefix should never conflict with prefixes of other defined mappings otherwise some of your entities cannot be found by Doctrine.

### alias

Doctrine offers a way to alias entity namespaces to simpler, shorter names to be used in DQL queries or for Repository access.

### is\_bundle

This option is **false** by default and it's considered a legacy option. It was only useful in previous Symfony versions, when it was recommended to use bundles to organize the application code.

## Custom Mapping Entities in a Bundle

Doctrine's `auto_mapping` feature loads annotation configuration from the `Entity/` directory of each bundle *and* looks for other formats (e.g. YAML, XML) in the `Resources/config/doctrine` directory.

If you store metadata somewhere else in your bundle, you can define your own mappings, where you tell Doctrine exactly *where* to look, along with some other configurations.

If you're using the `auto_mapping` configuration, you just need to overwrite the configurations you want. In this case it's important that the key of the mapping configurations corresponds to the name of the bundle.

For example, suppose you decide to store your XML configuration for `AppBundle` entities in the `@AppBundle/SomeResources/config/doctrine` directory instead:

Listing 2-7

```
1 doctrine:
2   # ...
3   orm:
4     # ...
5     auto_mapping: true
6     mappings:
7       # ...
8       AppBundle:
9         type: xml
10        dir: SomeResources/config/doctrine
```

## Mapping Entities Outside of a Bundle

For example, the following looks for entity classes in the `Entity` namespace in the `src/Entity` directory and gives them an `App` alias (so you can say things like `App:Post`):

Listing 2-8

```
1 doctrine:
2   # ...
3   orm:
4     # ...
5     mappings:
6       # ...
7       SomeEntityNamespace:
8         type: annotation
9         dir: '%kernel.project_dir%/src/Entity'
10        is_bundle: false
11        prefix: App\Entity
12        alias: App
```

## Detecting a Mapping Configuration Format

If the `type` on the bundle configuration isn't set, the `DoctrineBundle` will try to detect the correct mapping configuration format for the bundle.

`DoctrineBundle` will look for files matching `*.orm.[FORMAT]` (e.g. `Post.orm.yaml`) in the configured `dir` of your mapping (if you're mapping a bundle, then `dir` is relative to the bundle's directory).

The bundle looks for (in this order) XML, YAML and PHP files. Using the `auto_mapping` feature, every bundle can have only one configuration format. The bundle will stop as soon as it locates one.

If it wasn't possible to determine a configuration format for a bundle, the `DoctrineBundle` will check if there is an `Entity` folder in the bundle's root directory. If the folder exist, Doctrine will fall back to using an annotation driver.

## Default Value of Dir

If **dir** is not specified, then its default value depends on which configuration driver is being used. For drivers that rely on the PHP files (annotation, staticphp) it will be **[Bundle]/Entity**. For drivers that are using configuration files (XML, YAML, ...) it will be **[Bundle]/Resources/config/doctrine**.

If the **dir** configuration is set and the **is\_bundle** configuration is **true**, the DoctrineBundle will prefix the **dir** configuration with the path of the bundle.

## Chapter 3

# SecurityBundle Configuration ("security")

The security system is one of the most powerful parts of Symfony and can largely be controlled via its configuration.

## Full Default Configuration

The following is the full default configuration for the security system. Each part will be explained in the next section.

Listing 3-1

```
1 # config/packages/security.yaml
2 security:
3     access_denied_url: ~ # Example: /foo/error403
4
5     # strategy can be: none, migrate, invalidate
6     session_fixation_strategy: migrate
7     hide_user_not_found: true
8     always_authenticate_before_granting: false
9     erase_credentials: true
10    access_decision_manager:
11        strategy: affirmative # One of affirmative, consensus, unanimous
12        allow_if_all_abstain: false
13        allow_if_equal_granted_denied: true
14
15    encoders:
16        # Examples:
17        App\Entity\User1: sha512
18        App\Entity\User2:
19            algorithm: sha512
20            encode_as_base64: true
21            iterations: 5000
22
23        # PBKDF2 encoder
24        # see the note about PBKDF2 below for details on security and speed
25        App\Entity\User3:
26            algorithm: pbkdf2
27            hash_algorithm: sha512
28            encode_as_base64: true
29            iterations: 1000
30            key_length: 40
31
32        # Example options/values for what a custom encoder might look like
```

```

33     App\Entity\User4:
34         id: App\Security\MyPasswordEncoder
35
36     # BCrypt encoder
37     # see the note about bcrypt below for details on specific dependencies
38     App\Entity\User5:
39         algorithm: bcrypt
40         cost: 13
41
42     # Plaintext encoder
43     # it does not do any encoding
44     App\Entity\User6:
45         algorithm: plaintext
46         ignore_case: false
47
48     # Argon2i encoder
49     Acme\DemoBundle\Entity\User6:
50         algorithm: argon2i
51
52 providers: # Required
53     # Examples:
54     my_in_memory_provider:
55         memory:
56             users:
57                 foo:
58                     password: foo
59                     roles: ROLE_USER
60                 bar:
61                     password: bar
62                     roles: [ROLE_USER, ROLE_ADMIN]
63
64     my_entity_provider:
65         entity:
66             class: App\Entity\User7
67             property: username
68             # name of a non-default entity manager
69             manager_name: ~
70
71     my_ldap_provider:
72         ldap:
73             service: ~
74             base_dn: ~
75             search_dn: ~
76             search_password: ~
77             default_roles: 'ROLE_USER'
78             uid_key: 'sAMAccountName'
79             filter: '({uid_key}={username})'
80
81     # Example custom provider
82     my_some_custom_provider: ~
83         id: ~
84
85     # Chain some providers
86     my_chain_provider:
87         chain:
88             providers: [ my_in_memory_provider, my_entity_provider ]
89
90 firewalls: # Required
91     # Examples:
92     somename:
93         pattern: .*
94         # restrict the firewall to a specific host
95         host: admin\.example\.com
96         # restrict the firewall to specific HTTP methods
97         methods: [GET, POST]
98         request_matcher: some.service.id
99         access_denied_url: /foo/error403
100        access_denied_handler: some.service.id
101        entry_point: some.service.id
102        provider: some_key_from_above
103        # manages where each firewall stores session information

```

```

104     # See "Firewall Context" below for more details
105     context: context_key
106     stateless: false
107     x509:
108         provider: some_key_from_above
109     remote_user:
110         provider: some_key_from_above
111     http_basic:
112         provider: some_key_from_above
113     http_basic_ldap:
114         provider:     some_key_from_above
115         service:     ldap
116         dn_string:    '{username}'
117         query_string: ~
118     http_digest:
119         provider: some_key_from_above
120     guard:
121         # A key from the "providers" section of your security config, in case your user provider is
122         different than the firewall
123         provider:     ~
124
125         # A service id (of one of your authenticators) whose start() method should be called when an
126         anonymous user hits a page that requires authentication
127         entry_point:  null
128
129         # An array of service ids for all of your "authenticators"
130         authenticators: []
131     form_login:
132         # submit the login form here
133         check_path: /login_check

281         ROLE_SUPERADMIN:    [ROLE_ADMIN]

```

## Form Login Configuration

When using the `form_login` authentication listener beneath a firewall, there are several common options for configuring the "form login" experience.

For even more details, see *How to Customize Redirect After Form Login*.

### The Login Form and Process

#### `login_path`

**type:** string **default:** /login

This is the route or path that the user will be redirected to (unless `use_forward` is set to `true`) when they try to access a protected resource but isn't fully authenticated.

This path **must** be accessible by a normal, un-authenticated user, else you may create a redirect loop. For details, see "Avoid Common Pitfalls".

#### `check_path`

**type:** string **default:** /login\_check

This is the route or path that your login form must submit to. The firewall will intercept any requests (POST requests only, by default) to this URL and process the submitted login credentials.

Be sure that this URL is covered by your main firewall (i.e. don't create a separate firewall just for `check_path` URL).

`use_forward`

**type: boolean default: false**

If you'd like the user to be forwarded to the login form instead of being redirected, set this option to `true`.

`username_parameter`

**type: string default: `_username`**

This is the field name that you should give to the username field of your login form. When you submit the form to `check_path`, the security system will look for a POST parameter with this name.

`password_parameter`

**type: string default: `_password`**

This is the field name that you should give to the password field of your login form. When you submit the form to `check_path`, the security system will look for a POST parameter with this name.

`post_only`

**type: boolean default: true**

By default, you must submit your login form to the `check_path` URL as a POST request. By setting this option to `false`, you can send a GET request to the `check_path` URL.

## Redirecting after Login

`always_use_default_target_path`

**type: boolean default: false**

If `true`, users are always redirected to the default target path regardless of the previous URL that was stored in the session.

`default_target_path`

**type: string default: `/`**

The page users are redirected to when there is no previous page stored in the session (for example, when the users browse the login page directly).

`target_path_parameter`

**type: string default: `_target_path`**

When using a login form, if you include an HTML element to set the target path, this option lets you change the name of the HTML element itself.

`use_referer`

**type: boolean default: false**

If **true**, the user is redirected to the value stored in the `HTTP_REFERER` header when no previous URL was stored in the session. If the referrer URL is the same as the one generated with the `login_path` route, the user is redirected to the `default_target_path` to avoid a redirection loop.

For historical reasons, and to match the misspelling of the HTTP standard, the option is called `use_referer` instead of `use_referrer`.

## Logout Configuration

`invalidate_session`

**type:** boolean **default:** true

By default, when users log out from any firewall, their sessions are invalidated. This means that logging out from one firewall automatically logs them out from all the other firewalls.

The `invalidate_session` option allows to redefine this behavior. Set this option to **false** in every firewall and the user will only be logged out from the current firewall and not the other ones.

## LDAP functionality

There are several options for connecting against an LDAP server, using the `form_login_ldap` and `http_basic_ldap` authentication providers or the `ldap` user provider.

For even more details, see *Authenticating against an LDAP server*.

### Authentication

You can authenticate to an LDAP server using the LDAP variants of the `form_login` and `http_basic` authentication providers. Simply use `form_login_ldap` and `http_basic_ldap`, which will attempt to **bind** against a LDAP server instead of using password comparison.

Both authentication providers have the same arguments as their normal counterparts, with the addition of two configuration keys:

`service`

**type:** string **default:** ldap

This is the name of your configured LDAP client.

`dn_string`

**type:** string **default:** {username}

This is the string which will be used as the bind DN. The `{username}` placeholder will be replaced with the user-provided value (their login). Depending on your LDAP server's configuration, you may need to override this value.

`query_string`

**type:** string **default:** null

This is the string which will be used to query for the DN. The `{username}` placeholder will be replaced with the user-provided value (their login). Depending on your LDAP server's configuration, you will need to override this value. This setting is only necessary if the user's DN cannot be derived statically using the `dn_string` config option.

## User provider

Users will still be fetched from the configured user provider. If you wish to fetch your users from a LDAP server, you will need to use the `ldap` user provider, in addition to one of the two authentication providers (`form_login_ldap` or `http_basic_ldap`).

```
Listing 3-2 1 # config/packages/security.yaml
2 security:
3     # ...
4
5     providers:
6         my_ldap_users:
7             ldap:
8                 service: ldap
9                 base_dn: 'dc=symfony,dc=com'
10                search_dn: '%ldap.search_dn%'
11                search_password: '%ldap.search_password%'
12                default_roles: ''
13                uid_key: 'uid'
14                filter: '(&({uid_key}={username})(objectclass=person)(ou=Users))'
```

## Using the PBKDF2 Encoder: Security and Speed

The `PBKDF2`<sup>1</sup> encoder provides a high level of Cryptographic security, as recommended by the National Institute of Standards and Technology (NIST).

You can see an example of the `pbkdf2` encoder in the YAML block on this page.

But using PBKDF2 also warrants a warning: using it (with a high number of iterations) slows down the process. Thus, PBKDF2 should be used with caution and care.

A good configuration lies around at least 1000 iterations and sha512 for the hash algorithm.

## Using the BCrypt Password Encoder

```
Listing 3-3 1 # config/packages/security.yaml
2 security:
3     # ...
4
5     encoders:
6         Symfony\Component\Security\Core\User\User:
7             algorithm: bcrypt
8             cost: 15
```

The `COST` can be in the range of **4-31** and determines how long a password will be encoded. Each increment of `COST` *doubles* the time it takes to encode a password.

If you don't provide the `COST` option, the default cost of **13** is used.

---

1. <https://en.wikipedia.org/wiki/PBKDF2>

You can change the cost at any time — even if you already have some passwords encoded using a different cost. New passwords will be encoded using the new cost, while the already encoded ones will be validated using a cost that was used back when they were encoded.

A salt for each new password is generated automatically and need not be persisted. Since an encoded password contains the salt used to encode it, persisting the encoded password alone is enough.

BCrypt encoded passwords are **60** characters long, so make sure to allocate enough space for them to be persisted.

A simple technique to make tests much faster when using BCrypt is to set the cost to **4**, which is the minimum value allowed, in the **test** environment configuration.

## Using the Argon2i Password Encoder

To use this encoder, you either need to use PHP version 7.2 or install the *libsodium*<sup>2</sup> extension.

Listing 3-4

```
1 # app/config/security.yml
2 security:
3   # ...
4
5   encoders:
6     Symfony\Component\Security\Core\User\User:
7       algorithm: argon2i
```

A salt for each new password is generated automatically and need not be persisted. Since an encoded password contains the salt used to encode it, persisting the encoded password alone is enough.

Argon2i encoded passwords are **96** characters long, but due to the hashing requirements saved in the resulting hash this may change in the future.

## Firewall Context

Most applications will only need one firewall. But if your application *does* use multiple firewalls, you'll notice that if you're authenticated in one firewall, you're not automatically authenticated in another. In other words, the systems don't share a common "context": each firewall acts like a separate security system.

However, each firewall has an optional **context** key (which defaults to the name of the firewall), which is used when storing and retrieving security data to and from the session. If this key were set to the same value across multiple firewalls, the "context" could actually be shared:

Listing 3-5

```
1 # config/packages/security.yaml
2 security:
```

---

2. <https://pecl.php.net/package/libsodium>

```
3 # ...
4
5 firewalls:
6   somename:
7     # ...
8     context: my_context
9   othername:
10    # ...
11    context: my_context
```

The firewall context key is stored in session, so every firewall using it must set its **stateless** option to **false**. Otherwise, the context is ignored and you won't be able to authenticate on multiple firewalls at the same time.

## Chapter 4

# SwiftmailerBundle Configuration ("swiftmailer")

This reference document is a work in progress. It should be accurate, but all options are not yet fully covered. For a full list of the default configuration options, see [Full Default Configuration](#)

The **swiftmailer** key configures Symfony's integration with Swift Mailer, which is responsible for creating and delivering email messages.

The following section lists all options that are available to configure a mailer. It is also possible to configure several mailers (see [Using Multiple Mailers](#)).

## Configuration

- url
- transport
- username
- password
- command
- host
- port
- timeout
- source\_ip
- local\_domain
- encryption
- auth\_mode
- **spool**
  - type
  - path

- sender\_address
- **antiflood**
  - threshold
  - sleep
- delivery\_addresses
- delivery\_whitelist
- disable\_delivery
- logging

## url

**type:** string

The entire SwiftMailer configuration using a DSN-like URL format.

Example: `smtp://user:pass@host:port/?timeout=60&encryption=ssl&auth_mode=login&...`

## transport

**type:** string **default:** smtp

The exact transport method to use to deliver emails. Valid values are:

- smtp
- gmail (see Using Gmail to Send Emails)
- mail (deprecated in SwiftMailer since version 5.4.5)
- sendmail
- null (same as setting `disable_delivery` to `true`)

## username

**type:** string

The username when using `smtp` as the transport.

## password

**type:** string

The password when using `smtp` as the transport.

## command

**type:** string **default:** /usr/sbin/sendmail -bs

Command to be executed by `sendmail` transport.

## host

**type:** string **default:** localhost

The host to connect to when using `smtp` as the transport.

## port

**type:** string **default:** 25 or 465 (depending on encryption)

The port when using **smtp** as the transport. This defaults to 465 if encryption is **ssl** and 25 otherwise.

## timeout

**type:** integer

The timeout in seconds when using **smtp** as the transport.

## source\_ip

**type:** string

The source IP address when using **smtp** as the transport.

## local\_domain

**type:** string

*New in version 2.4.0:* The **local\_domain** option was introduced in SwiftMailerBundle 2.4.0.

The domain name to use in **HELO** command.

## encryption

**type:** string

The encryption mode to use when using **smtp** as the transport. Valid values are **tls**, **ssl**, or **null** (indicating no encryption).

## auth\_mode

**type:** string

The authentication mode to use when using **smtp** as the transport. Valid values are **plain**, **login**, **cram-md5**, or **null**.

## spool

For details on email spooling, see *How to Spool Emails*.

## type

**type:** string **default:** file

The method used to store spooled messages. Valid values are **memory** and **file**. A custom spool should be possible by creating a service called **swiftmailer.spool.myspool** and setting this value to **myspool**.

## path

**type:** string **default:** %kernel.cache\_dir%/swiftmailer/spool

When using the **file** spool, this is the path where the spooled messages will be stored.

`sender_address`

**type:** string

If set, all messages will be delivered with this address as the "return path" address, which is where bounced messages should go. This is handled internally by Swift Mailer's `Swift_Plugins_ImpersonatePlugin` class.

`antiflood`

`threshold`

**type:** integer **default:** 99

Used with `Swift_Plugins_AntiFloodPlugin`. This is the number of emails to send before restarting the transport.

`sleep`

**type:** integer **default:** 0

Used with `Swift_Plugins_AntiFloodPlugin`. This is the number of seconds to sleep for during a transport restart.

`delivery_addresses`

**type:** array

In previous versions, this option was called `delivery_address`.

If set, all email messages will be sent to these addresses instead of being sent to their actual recipients. This is often useful when developing. For example, by setting this in the `config/packages/dev/swiftmailer.yaml` file, you can guarantee that all emails sent during development go to one or more some specific accounts.

This uses `Swift_Plugins_RedirectingPlugin`. Original recipients are available on the `X-Swift-To`, `X-Swift-Cc` and `X-Swift-Bcc` headers.

`delivery_whitelist`

**type:** array

Used in combination with `delivery_address` or `delivery_addresses`. If set, emails matching any of these patterns will be delivered like normal, as well as being sent to `delivery_address` or `delivery_addresses`. For details, see the [How to Work with Emails during Development](#) article.

`disable_delivery`

**type:** boolean **default:** false

If true, the `transport` will automatically be set to `null` and no emails will actually be delivered.

## logging

**type:** boolean **default:** `%kernel.debug%`

If true, Symfony's data collector will be activated for Swift Mailer and the information will be available in the profiler.

The following options can be set via environment variables using the `%env()%` syntax: `url`, `transport`, `username`, `password`, `host`, `port`, `timeout`, `source_ip`, `local_domain`, `encryption`, `auth_mode`. For details, see the *How to Set external Parameters in the Service Container* article.

## Full Default Configuration

Listing 4-1

```
1 swiftmailer:
2   transport:      smtp
3   username:       ~
4   password:       ~
5   host:           localhost
6   port:           false
7   encryption:     ~
8   auth_mode:      ~
9   spool:
10    type:          file
11    path:          '%kernel.cache_dir%/swiftmailer/spool'
12  sender_address: ~
13  antiflood:
14    threshold:     99
15    sleep:         0
16  delivery_addresses: []
17  disable_delivery: ~
18  logging:         '%kernel.debug%'
```

## Using Multiple Mailers

You can configure multiple mailers by grouping them under the `mailers` key (the default mailer is identified by the `default_mailer` option):

Listing 4-2

```
1 swiftmailer:
2   default_mailer: second_mailer
3   mailers:
4     first_mailer:
5       # ...
6     second_mailer:
7       # ...
```

Each mailer is registered automatically as a service with these IDs:

Listing 4-3

```
1 // ...
2
3 // returns the first mailer
4 $container->get('swiftmailer.mailer.first_mailer');
5
6 // also returns the second mailer since it is the default mailer
7 $container->get('swiftmailer.mailer');
8
9 // returns the second mailer
10 $container->get('swiftmailer.mailer.second_mailer');
```

When configuring multiple mailers, options must be placed under the appropriate mailer key of the configuration instead of directly under the **swiftmailer** key.

When using autowiring only the default mailer is injected when type-hinting some argument with the `\Swift_Mailer` class. If you need to inject a different mailer in some service, use any of these alternatives based on the service binding feature:

Listing 4-4

```
1 # config/services.yaml
2 services:
3   _defaults:
4     bind:
5       # this injects the second mailer when type-hinting constructor arguments with \Swift_Mailer
6       \Swift_Mailer: '@swiftmailer.mailer.second_mailer'
7       # this injects the second mailer when a service constructor argument is called $specialMailer
8       $specialMailer: '@swiftmailer.mailer.second_mailer'
9
10  App\Some\Service:
11    # this injects the second mailer only for this argument of this service
12    $differentMailer: '@swiftmailer.mailer.second_mailer'
13
14  # ...
```

## Chapter 5

# TwigBundle Configuration ("twig")

Listing 5-1

```
1 # config/packages/twig.yaml
2 twig:
3     exception_controller: twig.controller.exception:showAction
4
5     form_themes:
6
7         # Default:
8         - form_div_layout.html.twig
9
10        # Bootstrap:
11        - bootstrap_3_layout.html.twig
12        - bootstrap_3_horizontal_layout.html.twig
13        - bootstrap_4_layout.html.twig
14        - bootstrap_4_horizontal_layout.html.twig
15
16        # Foundation
17        - foundation_5_layout.html.twig
18
19        # Example:
20        - form.html.twig
21
22    globals:
23
24        # Examples:
25        foo: '@bar'
26        pi: 3.14
27
28        # Example options, but the easiest use is as seen above
29        some_variable_name:
30            # a service id that should be the value
31            id: ~
32            # set to service or leave blank
33            type: ~
34            value: ~
35    autoescape: ~
36
37    # See http://twig.sensiolabs.org/doc/
38    recipes.html#using-the-template-name-to-set-the-default-escaping-strategy
39    autoescape_service: ~ # Example: 'my_service'
40    autoescape_service_method: ~ # use in combination with autoescape_service option
41    base_template_class: ~ # Example: Twig_Template
42    cache: '%kernel.cache_dir%/twig'
43    charset: '%kernel.charset%'
```

```

44     debug:                               '%kernel.debug%'
45     strict_variables:                     ~
46     auto_reload:                           ~
47     optimizations:                         ~
48     default_path: '%kernel.project_dir%/templates'
49     paths:
50         '%kernel.project_dir%/vendor/acme/foo-bar/templates': foo_bar
51
52     date:
53         format: d.m.Y, H:i:s
54         interval_format: '%%d days'
55         timezone: Asia/Tokyo
56     number_format:
57         decimals: 2
58         decimal_point: ','
59         thousands_separator: '.'

```

## Configuration

### auto\_reload

**type:** boolean **default:** '%kernel.debug%'

If **true**, whenever a template is rendered, Symfony checks first if its source code has changed since it was compiled. If it has changed, the template is compiled again automatically.

### autoescape

**type:** boolean or string **default:** 'name'

If set to **false**, automatic escaping is disabled (you can still escape each content individually in the templates).

Setting this option to **false** is dangerous and it will make your application vulnerable to XSS exploits because most third-party bundles assume that auto-escaping is enabled and they don't escape contents themselves.

If set to a string, the template contents are escaped using the strategy with that name. Allowed values are **html**, **js**, **css**, **url**, **html\_attr** and **name**. The default value is **name**. This strategy escapes contents according to the template name extension (e.g. it uses **html** for **\*.html.twig** templates and **js** for **\*.js.html** templates).

See `autoescape_service` and `autoescape_service_method` to define your own escaping strategy.

### autoescape\_service

**type:** string **default:** null

As of Twig 1.17, the escaping strategy applied by default to the template is determined during compilation time based on the filename of the template. This means for example that the contents of a **\*.html.twig** template are escaped for HTML and the contents of **\*.js.twig** are escaped for JavaScript.

This option allows to define the Symfony service which will be used to determine the default escaping applied to the template.

### `autoescape_service_method`

**type:** string **default:** null

If `autoescape_service` option is defined, then this option defines the method called to determine the default escaping applied to the template.

### `base_template_class`

**type:** string **default:** 'Twig\_Template'

Twig templates are compiled into PHP classes before using them to render contents. This option defines the base class from which all the template classes extend. Using a custom base template is discouraged because it will make your application harder to maintain.

### `cache`

**type:** string **default:** '%kernel.cache\_dir%/twig'

Before using the Twig templates to render some contents, they are compiled into regular PHP code. Compilation is a costly process, so the result is cached in the directory defined by this configuration option.

Set this option to `null` to disable Twig template compilation. However, this is not recommended; not even in the `dev` environment, because the `auto_reload` option ensures that cached templates which have changed get compiled again.

### `charset`

**type:** string **default:** '%kernel.charset%'

The charset used by the template files. By default it's the same as the value of the `kernel.charset` container parameter, which is `UTF-8` by default in Symfony applications.

### `date`

These options define the default values used by the `date` filter to format date and time values. They are useful to avoid passing the same arguments on every `date` filter call.

#### `format`

**type:** string **default:** F j, Y H:i

The format used by the `date` filter to display values when no specific format is passed as argument.

#### `internal_format`

**type:** string **default:** %d days

The format used by the `date` filter to display `DateInterval` instances when no specific format is passed as argument.

## timezone

**type:** string **default:** (the value returned by `date_default_timezone_get()`)

The timezone used when formatting date values with the `date` filter and no specific timezone is passed as argument.

## debug

**type:** boolean **default:** '%kernel.debug%'

If `true`, the compiled templates include a `__toString()` method that can be used to display their nodes.

## exception\_controller

**type:** string **default:** `twig.controller.exception:showAction`

This is the controller that is activated after an exception is thrown anywhere in your application. The default controller (*ExceptionController*<sup>1</sup>) is what's responsible for rendering specific templates under different error conditions (see *How to Customize Error Pages*). Modifying this option is advanced. If you need to customize an error page you should use the previous link. If you need to perform some behavior on an exception, you should add a listener to the `kernel.exception` event (see `kernel.event_listener`).

## number\_format

These options define the default values used by the `number_format` filter to format numeric values. They are useful to avoid passing the same arguments on every `number_format` filter call.

### decimals

**type:** integer **default:** 0

The number of decimals used to format numeric values when no specific number is passed as argument to the `number_format` filter.

### decimal\_point

**type:** string **default:** .

The character used to separate the decimals from the integer part of numeric values when no specific character is passed as argument to the `number_format` filter.

### thousands\_separator

**type:** string **default:** ,

The character used to separate every group of thousands in numeric values when no specific character is passed as argument to the `number_format` filter.

## optimizations

**type:** int **default:** -1

---

1. <https://api.symfony.com/4.0/Symfony/Bundle/TwigBundle/Controller/ExceptionController.html>

Twig includes an extension called **optimizer** which is enabled by default in Symfony applications. This extension analyzes the templates to optimize them when being compiled. For example, if your template doesn't use the special **loop** variable inside a **for** tag, this extension removes the initialization of that unused variable.

By default, this option is **-1**, which means that all optimizations are turned on. Set it to **0** to disable all the optimizations. You can even enable or disable these optimizations selectively, as explained in the Twig documentation about *the optimizer extension*<sup>2</sup>.

## default\_path

**type:** string **default:** '%kernel.project\_dir%/templates'

The default directory where Symfony will look for Twig templates.

## paths

**type:** array **default:** null

This option defines the directories where Symfony will look for Twig templates in addition to the default locations. Symfony looks for the templates in the following order:

1. The directories defined in this option;
2. The `Resources/views/` directories of the bundles used in the application;
3. The `src/Resources/views/` directory of the application;
4. The directory defined in the `default_path` option.

The values of the `paths` option are defined as **key: value** pairs where the **value** part can be **null**. For example:

```
Listing 5-2 1 # config/packages/twig.yaml
2 twig:
3   # ...
4   paths:
5     '%kernel.project_dir%/vendor/acme/foo-bar/templates': ~
```

The directories defined in the `paths` option have more priority than the default directories defined by Symfony. In the above example, if the template exists in the `acme/foo-bar/templates/` directory inside your application's `vendor/`, it will be used by Symfony.

If you provide a value for any path, Symfony will consider it the Twig namespace for that directory:

```
Listing 5-3 1 # config/packages/twig.yaml
2 twig:
3   # ...
4   paths:
5     '%kernel.project_dir%/vendor/acme/foo-bar/templates': 'foo_bar'
```

This option is useful to not mess with the default template directories defined by Symfony. Besides, it simplifies how you refer to those templates:

```
Listing 5-4 1 @foo_bar/template_name.html.twig
```

## strict\_variables

**type:** boolean **default:** false

---

2. <http://twig.sensiolabs.org/doc/api.html#optimizer-extension>

If set to **true**, Symfony shows an exception whenever a Twig variable, attribute or method doesn't exist. If set to **false** these errors are ignored and the non-existing values are replaced by **null**.

## Chapter 6

# MonologBundle Configuration ("monolog")

For a full list of handler types and related configuration options, see *Monolog Configuration*<sup>1</sup>.

## Full Default Configuration

```
Listing 6-1 1 # config/packages/prod/monolog.yaml
2 monolog:
3     handlers:
4
5         # Examples:
6     syslog:
7         type:                stream
8         path:                /var/log/symfony.log
9         level:                ERROR
10        bubble:               false
11        formatter:            my_formatter
12    main:
13        type:                  fingers_crossed
14        action_level:          WARNING
15        # By default, buffer_size is unlimited (0), which could
16        # generate huge logs.
17        buffer_size:           0
18        handler:                custom
19    console:
20        type:                  console
21        verbosity_levels:
22            VERBOSITY_NORMAL:    WARNING
23            VERBOSITY_VERBOSE:   NOTICE
24            VERBOSITY_VERY_VERBOSE: INFO
25            VERBOSITY_DEBUG:     DEBUG
26    custom:
27        type:                  service
28        id:                    my_handler
29
30        # Default options and values for some "my_custom_handler"
31        # Note: many of these options are specific to the "type".
32        # For example, the 'service' type doesn't use any options
33        # except id and channels
```

---

1. <https://github.com/symfony/monolog-bundle/blob/master/DependencyInjection/Configuration.php>

```

34     my_custom_handler:
35         type: ~ # Required
36         id: ~
37         priority: 0
38         level: DEBUG
39         bubble: true
40         path: '%kernel.logs_dir%/%kernel.environment%.log'
41         ident: false
42         facility: user
43         max_files: 0
44         action_level: WARNING
45         activation_strategy: ~
46         stop_buffering: true
47         buffer_size: 0
48         handler: ~
49         members: []
50         channels:
51             type: ~
52             elements: ~
53         from_email: ~
54         to_email: ~
55         subject: ~
56         mailer: ~
57         email_prototype:
58             id: ~ # Required (when the email_prototype is used)
59             method: ~
60         formatter: ~
61     # Set to false to use seconds (instead of microseconds) in
62     # the logs (gives a small performance boost).
63     use_microseconds: true

```

When the profiler is enabled, a handler is added to store the logs' messages in the profiler. The profiler uses the name "debug" so it is reserved and cannot be used in the configuration.

## Chapter 7

# WebProfilerBundle Configuration ("web\_profiler")

The WebProfilerBundle provides detailed technical information about each request execution and displays it in both the web debug toolbar and the profiler.

The web debug toolbar is not available for responses of type **StreamedResponse**.

## Configuration

- toolbar
- intercept\_redirects
- excluded\_ajax\_paths

### toolbar

**type:** boolean **default:** false

It enables and disables the toolbar entirely. Usually you set this to **true** in the **dev** and **test** environments and to **false** in the **prod** environment.

### intercept\_redirects

**type:** boolean **default:** false

If a redirect occurs during an HTTP response, the browser follows it automatically and you won't see the toolbar or the profiler of the original URL, only the redirected URL.

When setting this option to **true**, the browser *stops* before making any redirection and shows you the URL which is going to redirect to, its toolbar, and its profiler. Once you've inspected the toolbar/profiler data, you can click on the given link to perform the redirect.

`excluded_ajax_paths`

**type:** string **default:** `'^/(app(_[\w]+)?\.\php/)?_wdt'`

When the toolbar logs Ajax requests, it matches their URLs against this regular expression. If the URL matches, the request is not displayed in the toolbar. This is useful when the application makes lots of Ajax requests or they are heavy and you want to exclude some of them.

## Full Default Configuration

Listing 7-1

```
1 # config/packages/dev/web_profiler.yaml
2 web_profiler:
3     toolbar: false
4     intercept_redirects: false
5     excluded_ajax_paths: ^/(app(_[\w]+)?\.\php/)?_wdt
```

## Chapter 8

# DebugBundle Configuration ("debug")

The DebugBundle allows greater integration of the *VarDumper component* in the Symfony full-stack framework and can be configured under the `debug` key in your application configuration. When using XML, you must use the `http://symfony.com/schema/dic/debug` namespace.

The XSD schema is available at <http://symfony.com/schema/dic/debug/debug-1.0.xsd>.

## Configuration

- `max_items`
- `min_depth`
- `max_string_length`
- `dump_destination`

### `max_items`

**type:** integer **default:** 2500

This is the maximum number of items to dump. Setting this option to `-1` disables the limit.

### `min_depth`

**type:** integer **default:** 1

Configures the minimum tree depth until which all items are guaranteed to be cloned. After this depth is reached, only `max_items` items will be cloned. The default value is `1`, which is consistent with older Symfony versions.

### `max_string_length`

**type:** integer **default:** -1

This option configures the maximum string length before truncating the string. The default value (-1) means that strings are never truncated.

## dump\_destination

**type:** string **default:** null

Configures the output destination of the dumps.

By default, the dumps are shown in the toolbar. Since this is not always possible (e.g. when working on a JSON API), you can have an alternate output destination for dumps. Typically, you would set this to **php://stderr**:

Listing 8-1

```
1 # config/packages/debug.yaml
2 debug:
3     dump_destination: php://stderr
```

## Chapter 9

# Configuring in the Kernel

Some configuration can be done on the kernel class itself (located by default at `src/Kernel.php`). You can do this by overriding specific methods in the parent *Kernel*<sup>1</sup> class.

## Configuration

- Charset
- Kernel Name
- Project Directory
- Cache Directory
- Log Directory

## Charset

**type:** string **default:** UTF-8

This returns the charset that is used in the application. To change it, override the *getCharset()*<sup>2</sup> method and return another charset, for instance:

Listing 9-1

```
1 // src/Kernel.php
2 use Symfony\Component\HttpKernel\Kernel as BaseKernel;
3 // ...
4
5 class Kernel extends BaseKernel
6 {
7     public function getCharset()
8     {
9         return 'ISO-8859-1';
10    }
11 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Kernel.html>

2. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Kernel.html#method\\_getCharset](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Kernel.html#method_getCharset)

## Kernel Name

**type:** string **default:** SRC (i.e. the directory name holding the kernel class)

To change this setting, override the `getName()`<sup>3</sup> method. Alternatively, move your kernel into a different directory. For example, if you moved the kernel into a `foo/` directory (instead of `SRC/`), the kernel name will be `foo`.

The name of the kernel isn't usually directly important - it's used in the generation of cache files - and you probably will only change it when *using applications with multiple kernels*.

## Project Directory

**type:** string **default:** the directory of the project `composer.json`

This returns the root directory of your Symfony project. It's calculated as the directory where the main `composer.json` file is stored.

If for some reason the `composer.json` file is not stored at the root of your project, you can override the `getProjectDir()`<sup>4</sup> method to return the right project directory:

Listing 9-2

```
1 // src/Kernel.php
2 use Symfony\Component\HttpKernel\Kernel as BaseKernel;
3 // ...
4
5 class Kernel extends BaseKernel
6 {
7     // ...
8
9     public function getProjectDir()
10    {
11        return realpath(__DIR__.'/../');
12    }
13 }
```

## Cache Directory

**type:** string **default:** `$this->rootDir/cache/$this->environment`

This returns the path to the cache directory. To change it, override the `getCacheDir()`<sup>5</sup> method. Read "Override the cache Directory" for more information.

## Log Directory

**type:** string **default:** `$this->rootDir/log`

This returns the path to the log directory. To change it, override the `getLogDir()`<sup>6</sup> method. Read "Override the logs Directory" for more information.

---

6. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Kernel.html#method\\_getLogDir](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Kernel.html#method_getLogDir)

## Chapter 10

# Form Types Reference

A form is composed of *fields*, each of which are built with the help of a field *type* (e.g. `TextType`, `ChoiceType`, etc). Symfony comes standard with a large list of field types that can be used in your application.

## Supported Field Types

The following field types are natively available in Symfony:

### Text Fields

- `TextType`
- `TextareaType`
- `EmailType`
- `IntegerType`
- `MoneyType`
- `NumberType`
- `PasswordType`
- `PercentType`
- `SearchType`
- `UrlType`
- `RangeType`
- `TelType`
- `ColorType`

### Choice Fields

- `ChoiceType`
- `EntityType`
- `CountryType`
- `LanguageType`
- `LocaleType`
- `TimezoneType`

- *CurrencyType*

## Date and Time Fields

- *DateType*
- *DateIntervalType*
- *DateTimeType*
- *TimeType*
- *BirthdayType*

## Other Fields

- *CheckboxType*
- *FileType*
- *RadioType*

## Field Groups

- *CollectionType*
- *RepeatedType*

## Hidden Fields

- *HiddenType*

## Buttons

- *ButtonType*
- *ResetType*
- *SubmitType*

## Base Fields

- *FormType*

## Chapter 11

# TextType Field

The TextType field represents the most basic input text field.

Rendered as	input text field
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li></ul>
Parent type	<i>FormType</i>
Class	<i>TextType</i> <sup>1</sup>

## Inherited Options

These options inherit from the *FormType*:

**data**

**type:** mixed **default:** Defaults to field of the underlying structure.

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/TextType.html>

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 11-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 11-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 11-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 11-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 11-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 11-6 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}
3 }} }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 11-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

## Overridden Options

### compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

---

2. <http://diveintohtml5.info/forms.html>

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 12

# TextareaType Field

Renders a `textarea` HTML element.

Rendered as	textarea tag
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<i>TextType</i>
Class	<i>TextareaType</i> <sup>1</sup>

If you prefer to use an **advanced WYSIWYG editor** instead of a plain textarea, consider using the IvoryCKEditorBundle community bundle. Read *its documentation*<sup>2</sup> to learn how to integrate it in your Symfony application.

## Inherited Options

These options inherit from the *FormType*:

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/TextareaType.html>  
2. <https://symfony.com/doc/current/bundles/IvoryCKEditorBundle/index.html>

## attr

**type:** array **default:** array()

If you want to add extra attributes to an HTML field representation you can use the `attr` option. It's an associative array with HTML attributes as keys. This can be useful when you need to set a custom class for some widget:

```
Listing 12-1 $builder->add('body', TextareaType::class, array(  
    'attr' => array('class' => 'tinymce'),  
));
```

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the `data` option:

```
Listing 12-2 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;  
2 // ...  
3  
4 $builder->add('token', HiddenType::class, array(  
5     'data' => 'abcdef',  
6 ));
```

The `data` option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the `disabled` option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 12-3 $builder->add('name', null, array(  
    'required' => false,  
    'empty_data' => 'John Doe',  
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 12-4 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 12-5 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 12-6 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 12-7 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3         }) }}
```

## label\_format

**type: string default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 12-8 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the **mapped** option to **false**.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding **label** will also render with a **required** class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>4</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

3. <http://diveintohtml5.info/forms.html>

4. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 13

# EmailType Field

The `EmailType` field is a text field that is rendered using the HTML5 `<input type="email" />` tag.

Rendered as	input email field (a text box)
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<code>TextType</code>
Class	<code>EmailType</code> <sup>1</sup>

## Inherited Options

These options inherit from the `FormType`:

### data

**type:** **mixed default:** Defaults to field of the underlying structure.

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/EmailType.html>

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 13-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 13-2 $builder->add('name', null, array(
1     'required' => false,
2     'empty_data' => 'John Doe',
3 ));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 13-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 13-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 13-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 13-6 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}
3 }} }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 13-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a **required** class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

2. <http://diveintohtml5.info/forms.html>

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 14

# IntegerType Field

Renders an input "number" field. Basically, this is a text field that's good at handling data that's in an integer form. The input **number** field looks like a text box, except that - if the user's browser supports HTML5 - it will have some extra front-end functionality.

This field has different options on how to handle input values that aren't integers. By default, all non-integer values (e.g. 6.78) will round down (e.g. 6).

Rendered as	input number field
Options	<ul style="list-style-type: none"><li>• grouping</li><li>• rounding_mode</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li><li>• scale</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>IntegerType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/IntegerType.html>

## Field Options

### grouping

**type:** integer **default:** false

This value is used internally as the `NumberFormatter::GROUPING_USED` value when using PHP's `NumberFormatter` class. Its documentation is non-existent, but it appears that if you set this to `true`, numbers will be grouped with a comma or period (depending on your locale): `12345.123` would display as `12,345.123`.

### rounding\_mode

**type:** integer **default:** `IntegerToLocalizedStringTransformer::ROUND_DOWN`

By default, if the user enters a non-integer number, it will be rounded down. There are several other rounding methods and each is a constant on the *IntegerToLocalizedStringTransformer*:

- `IntegerToLocalizedStringTransformer::ROUND_DOWN` Round towards zero.
- `IntegerToLocalizedStringTransformer::ROUND_FLOOR` Round towards negative infinity.
- `IntegerToLocalizedStringTransformer::ROUND_UP` Round away from zero.
- `IntegerToLocalizedStringTransformer::ROUND_CEILING` Round towards positive infinity.
- `IntegerToLocalizedStringTransformer::ROUND_HALF_DOWN` Round towards the "nearest neighbor". If both neighbors are equidistant, round down.
- `IntegerToLocalizedStringTransformer::ROUND_HALF_EVEN` Round towards the "nearest neighbor". If both neighbors are equidistant, round towards the even neighbor.
- `IntegerToLocalizedStringTransformer::ROUND_HALF_UP` Round towards the "nearest neighbor". If both neighbors are equidistant, round up.

## Overridden Options

### compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

### scale

**type:** integer **default:** 0

This specifies how many decimals will be allowed until the field rounds the submitted value (via `rounding_mode`). This option inherits from *number* type and is overridden to `0` for `IntegerType`.

## Inherited Options

These options inherit from the *FormType*:

---

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/DataTransformer/IntegerToLocalizedStringTransformer.html>

## data

**type: mixed default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 14-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type: boolean default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type: mixed**

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 14-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 14-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the **city** field, use:

```
Listing 14-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 14-5 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 14-6 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 14-7 1 {{ form_label(form.name, 'Your name', {  
2 'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3 }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 14-8 1 // ...  
2 $profileFormBuilder->add('address', AddressType::class, array(  
3 'label_format' => 'form.address.%name%',  
4 ));  
5  
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(  
7 'label_format' => 'form.address.%name%',  
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

3. <http://diveintohtml5.info/forms.html>

## Chapter 15

# MoneyType Field

Renders an input text field and specializes in handling submitted "money" data.

This field type allows you to specify a currency, whose symbol is rendered next to the text field. There are also several other options for customizing how the input and output of the data is handled.

Rendered as	input text field
Options	<ul style="list-style-type: none"><li>• currency</li><li>• divisor</li><li>• grouping</li><li>• scale</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>MoneyType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/MoneyType.html>

## Field Options

### currency

**type:** string **default:** EUR

Specifies the currency that the money is being specified in. This determines the currency symbol that should be shown by the text box. Depending on the currency - the currency symbol may be shown before or after the input text field.

This can be any *3 letter ISO 4217 code*<sup>2</sup>. You can also set this to false to hide the currency symbol.

### divisor

**type:** integer **default:** 1

If, for some reason, you need to divide your starting value by a number before rendering it to the user, you can use the **divisor** option. For example:

```
Listing 15-1 1 use Symfony\Component\Form\Extension\Core\Type\MoneyType;
2 // ...
3
4 $builder->add('price', MoneyType::class, array(
5     'divisor' => 100,
6 ));
```

In this case, if the **price** field is set to **9900**, then the value **99** will actually be rendered to the user. When the user submits the value **99**, it will be multiplied by **100** and **9900** will ultimately be set back on your object.

### grouping

**type:** integer **default:** false

This value is used internally as the **NumberFormatter::GROUPING\_USED** value when using PHP's **NumberFormatter** class. Its documentation is non-existent, but it appears that if you set this to **true**, numbers will be grouped with a comma or period (depending on your locale): **12345.123** would display as **12,345.123**.

### scale

**type:** integer **default:** 2

If, for some reason, you need some scale other than 2 decimal places, you can modify this value. You probably won't need to do this unless, for example, you want to round to the nearest dollar (set the scale to 0).

## Overridden Options

### compound

**type:** boolean **default:** false

---

2. [https://en.wikipedia.org/wiki/ISO\\_4217](https://en.wikipedia.org/wiki/ISO_4217)

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

## Inherited Options

These options inherit from the *FormType*:

### data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 15-2 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 15-3 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 15-4 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 15-5 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 15-6 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 15-7 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 15-8 1 {{ form_label(form.name, 'Your name', {  
2 'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}  
3 ) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

Listing 15-9

```
1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the **street** field of both forms will use the **form.address.street** keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Form Variables

Variable	Type	Usage
money_pattern	string	The format to use to display the money, including the currency.

3. <http://diveintohtml5.info/forms.html>

## Chapter 16

# NumberType Field

Renders an input text field and specializes in handling number input. This type offers different options for the scale, rounding and grouping that you want to use for your number.

Rendered as	input text field
Options	<ul style="list-style-type: none"><li>• grouping</li><li>• scale</li><li>• rounding_mode</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>NumberType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/NumberType.html>

## Field Options

### grouping

**type:** integer **default:** false

This value is used internally as the `NumberFormatter::GROUPING_USED` value when using PHP's `NumberFormatter` class. Its documentation is non-existent, but it appears that if you set this to `true`, numbers will be grouped with a comma or period (depending on your locale): `12345.123` would display as `12,345.123`.

### scale

*New in version 2.7:* The `scale` option was introduced in Symfony 2.7. Prior to Symfony 2.7, it was known as `precision`.

**type:** integer **default:** Locale-specific (usually around 3)

This specifies how many decimals will be allowed until the field rounds the submitted value (via `rounding_mode`). For example, if `scale` is set to `2`, a submitted value of `20.123` will be rounded to, for example, `20.12` (depending on your `rounding_mode`).

### rounding\_mode

**type:** integer **default:** `NumberToLocalizedStringTransformer::ROUND_HALF_UP`

If a submitted number needs to be rounded (based on the `scale` option), you have several configurable options for that rounding. Each option is a constant on the *NumberToLocalizedStringTransformer*<sup>2</sup>:

- `NumberToLocalizedStringTransformer::ROUND_DOWN` Round towards zero.
- `NumberToLocalizedStringTransformer::ROUND_FLOOR` Round towards negative infinity.
- `NumberToLocalizedStringTransformer::ROUND_UP` Round away from zero.
- `NumberToLocalizedStringTransformer::ROUND_CEILING` Round towards positive infinity.
- `NumberToLocalizedStringTransformer::ROUND_HALF_DOWN` Round towards the "nearest neighbor". If both neighbors are equidistant, round down.
- `NumberToLocalizedStringTransformer::ROUND_HALF_EVEN` Round towards the "nearest neighbor". If both neighbors are equidistant, round towards the even neighbor.
- `NumberToLocalizedStringTransformer::ROUND_HALF_UP` Round towards the "nearest neighbor". If both neighbors are equidistant, round up.

## Overridden Options

### compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

---

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/DataTransformer/NumberToLocalizedStringTransformer.html>

## Inherited Options

These options inherit from the *FormType*:

### data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 16-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 16-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

Form data transformers will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 16-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 16-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## invalid\_message

**type:** `string` **default:** `This value is not valid`

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 16-5 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 16-6 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 16-7 1 {{ form_label(form.name, 'Your name', {  
2 'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}  
3 }} }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 16-8 1 // ...  
2 $profileFormBuilder->add('address', AddressType::class, array(  
3 'label_format' => 'form.address.%name%',  
4 ));  
5  
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(  
7 'label_format' => 'form.invoice.%name%',  
8 ));
```

```
7     'label_format' => 'form.address.%name%',  
8 );
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type: boolean default: true**

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default: true**

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

3. <http://diveintohtml5.info/forms.html>

## Chapter 17

# PasswordType Field

The `PasswordType` field renders an input password text box.

Rendered as	input password field
Options	<ul style="list-style-type: none"><li>• <code>always_empty</code></li></ul>
Overridden options	<ul style="list-style-type: none"><li>• <code>trim</code></li></ul>
Inherited options	<ul style="list-style-type: none"><li>• <code>disabled</code></li><li>• <code>empty_data</code></li><li>• <code>error_bubbling</code></li><li>• <code>error_mapping</code></li><li>• <code>label</code></li><li>• <code>label_attr</code></li><li>• <code>label_format</code></li><li>• <code>mapped</code></li><li>• <code>required</code></li></ul>
Parent type	<code>TextType</code>
Class	<code>PasswordType</code> <sup>1</sup>

## Field Options

`always_empty`

**type:** boolean **default:** true

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/PasswordType.html>

If set to true, the field will *always* render blank, even if the corresponding field has a value. When set to false, the password field will be rendered with the **value** attribute set to its true value only upon submission.

Put simply, if for some reason you want to render your password field *with* the password value already entered into the box, set this to false and submit the form.

## Overridden Options

### trim

**type:** boolean **default:** false

Unlike the rest of form types, the `PasswordType` doesn't apply the *trim* function to the value submitted by the user. This ensures that the password is merged back onto the underlying object exactly as it was typed by the user.

## Inherited Options

These options inherit from the `FormType`:

### disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** mixed

The default value is `' '` (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

Listing 17-1

```
$builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

---

2. <https://secure.php.net/manual/en/function.trim.php>

Form data transformers will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 17-2 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 17-3 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** `string` **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

Listing 17-4 1 `{{ form_label(form.name, 'Your name') }}`

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

Listing 17-5 1 `{{ form_label(form.name, 'Your name', {`  
2  `'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}`  
3 `}) }}`

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

Listing 17-6 1 `// ...`  
2 `$profileFormBuilder->add('address', AddressType::class, array(`  
3  `'label_format' => 'form.address.%name%',`  
4 `));`  
5  
6 `$invoiceFormBuilder->add('invoice', AddressType::class, array(`  
7  `'label_format' => 'form.address.%name%',`  
8 `));`

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

3. <http://diveintohtml5.info/forms.html>

## Chapter 18

# PercentType Field

The **PercentType** renders an input text field and specializes in handling percentage data. If your percentage data is stored as a decimal (e.g. **.95**), you can use this field out-of-the-box. If you store your data as a number (e.g. **95**), you should set the **type** option to **integer**.

This field adds a percentage sign "%" after the input box.

Rendered as	input text field
Options	<ul style="list-style-type: none"><li>• scale</li><li>• type</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>PercentType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/PercentType.html>

## Field Options

scale

**type:** integer **default:** 0

By default, the input numbers are rounded. To allow for more decimal places, use this option.

type

**type:** string **default:** fractional

This controls how your data is stored on your object. For example, a percentage corresponding to "55%", might be stored as `.55` or `55` on your object. The two "types" handle these two cases:

- `fractional` If your data is stored as a decimal (e.g. `.55`), use this type. The data will be multiplied by 100 before being shown to the user (e.g. `55`). The submitted data will be divided by 100 on form submit so that the decimal value is stored (`.55`);
- `integer` If your data is stored as an integer (e.g. `55`), then use this option. The raw value (`55`) is shown to the user and stored on your object. Note that this only works for integer values.

## Overridden Options

compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

## Inherited Options

These options inherit from the *FormType*:

data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 18-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the `disabled` option to `true`. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The default value is `' '` (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

Listing 18-2

```
$builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

Listing 18-3

```

1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

Listing 18-4

```

1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.*' => 'city',
4     ),
5 ));

```

## invalid\_message

**type: string default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type: array default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

Listing 18-5

```

1 $builder->add('some_field', SomeFormType::class, array(
2     // ...
3     'invalid_message' => 'You entered an invalid value, it should include %num% letters',
4     'invalid_message_parameters' => array('%num%' => 6),
5 ));

```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 18-6 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 18-7 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3         }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 18-8 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the **mapped** option to **false**.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding **label** will also render with a **required** class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

2. <http://diveintohtml5.info/forms.html>

## Chapter 19

# SearchType Field

This renders an `<input type="search" />` field, which is a text box with special functionality supported by some browsers.

Read about the input search field at [DiveIntoHTML5.info](http://diveintohtml5.info)<sup>1</sup>

Rendered as	input search field
Inherited options	<ul style="list-style-type: none"><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<i>TextType</i>
Class	<i>SearchType</i> <sup>2</sup>

## Inherited Options

These options inherit from the *FormType*:

**disabled**

**type:** boolean **default:** false

---

1. <http://diveintohtml5.info/forms.html#type-search>

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/SearchType.html>

If you don't want a user to modify the value of a field, you can set the `disabled` option to `true`. Any submitted value will be ignored.

## `empty_data`

**type:** `mixed`

The default value is `' '` (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

Listing 19-1

```
$builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## `error_bubbling`

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## `error_mapping`

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no `"matchingCityAndZipCode"` field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

Listing 19-2

```
1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
```

```

6         ),
7     ));
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```

Listing 19-3 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.*' => 'city',
4     ),
5 ));

```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```

Listing 19-4 1 {{ form_label(form.name, 'Your name') }}

```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```

Listing 19-5 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}

```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

Listing 19-6

```
1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>4</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

3. <http://diveintohtml5.info/forms.html>

4. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 20

# UrlType Field

The **UrlType** field is a text field that prepends the submitted value with a given protocol (e.g. **http://**) if the submitted value doesn't already have a protocol.

Rendered as	input url field
Options	<ul style="list-style-type: none"><li>• default_protocol</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<i>TextType</i>
Class	<i>UrlType</i> <sup>1</sup>

## Field Options

**default\_protocol**

**type:** string **default:** http

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/UrlType.html>

If a value is submitted that doesn't begin with some protocol (e.g. `http://`, `ftp://`, etc), this protocol will be prepended to the string when the data is submitted to the form.

## Inherited Options

These options inherit from the *FormType*:

### data

**type:** **mixed** **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 20-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### disabled

**type:** **boolean** **default:** **false**

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** **mixed**

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 20-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 20-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 20-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 20-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 20-6 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3         }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 20-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the **mapped** option to **false**.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding **label** will also render with a **required** class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

2. <http://diveintohtml5.info/forms.html>

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 21

# RangeType Field

The `RangeType` field is a slider that is rendered using the HTML5 `<input type="range" />` tag.

Rendered as	input range field (slider in HTML5 supported browser)
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<code>TextType</code>
Class	<code>RangeType</code> <sup>1</sup>

## Basic Usage

```
Listing 21-1 1 use Symfony\Component\Form\Extension\Core\Type\RangeType;
2 // ...
3
4 $builder->add('name', RangeType::class, array(
5     'attr' => array(
6         'min' => 5,
7         'max' => 50
8     )
9 ));
```

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/RangeType.html>

## Inherited Options

These options inherit from the *FormType*:

### attr

**type:** array **default:** array()

If you want to add extra attributes to an HTML field representation you can use the **attr** option. It's an associative array with HTML attributes as keys. This can be useful when you need to set a custom class for some widget:

```
Listing 21-2 $builder->add('body', TextareaType::class, array(  
    'attr' => array('class' => 'tinymce'),  
));
```

### data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 21-3 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;  
2 // ...  
3  
4 $builder->add('token', HiddenType::class, array(  
5     'data' => 'abcdef',  
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 21-4 $builder->add('name', null, array(  
    'required' => false,  
    'empty_data' => 'John Doe',  
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** **boolean** **default:** **false** unless the form is **compound**

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** **array** **default:** **array()**

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 21-5 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the **city** field, use:

Listing 21-6

```

1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.T' => 'city',
4     ),
5 ));

```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

Listing 21-7 

```
1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

Listing 21-8 

```

1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## mapped

**type: boolean default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type: boolean default:** true

2. <http://diveintohtml5.info/forms.html>

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 22

# TelType Field

The **TelType** field is a text field that is rendered using the HTML5 `<input type="tel">` tag. Following the recommended HTML5 behavior, the value of this type is not validated in any way, because formats for telephone numbers vary too much depending on each country.

Nevertheless it may be useful to use this type in web applications because some browsers (e.g. smartphone browsers) adapt the input keyboard to make it easier to input phone numbers.

Rendered as	input tel field (a text box)
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li><li>• trim</li></ul>
Parent type	<i>TextType</i>
Class	<i>TelType</i> <sup>1</sup>

## Inherited Options

These options inherit from the *FormType*:

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/TelType.html>

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 22-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 22-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 22-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the **city** field, use:

```
Listing 22-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 22-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 22-6 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}
3 }}}}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 22-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

### **%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

### **%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

2. <http://diveintohtml5.info/forms.html>

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 23

# ColorType Field

The **ColorType** field is a text field that is rendered using the HTML5 `<input type="color">` tag. Depending on each browser, the behavior of this form field can vary substantially. Some browsers display it as a simple text field, while others display a native color picker.

The value of the underlying `<input type="color">` field is always a 7-character string specifying an RGB color in lower case hexadecimal notation. That's why it's not possible to select semi-transparent colors with this element.

Rendered as	<code>input color</code> field (a text box)
Inherited options	<ul style="list-style-type: none"><li>• <code>data</code></li><li>• <code>disabled</code></li><li>• <code>empty_data</code></li><li>• <code>error_bubbling</code></li><li>• <code>error_mapping</code></li><li>• <code>label</code></li><li>• <code>label_attr</code></li><li>• <code>label_format</code></li><li>• <code>mapped</code></li><li>• <code>required</code></li><li>• <code>trim</code></li></ul>
Parent type	<i>TextType</i>
Class	<i>ColorType</i> <sup>1</sup>

## Inherited Options

These options inherit from the *FormType*:

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/ColorType.html>

## data

**type: mixed default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 23-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type: boolean default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type: mixed**

The default value is '' (the empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 23-2 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 23-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the **city** field, use:

```
Listing 23-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 23-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 23-6 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}
3 }}}}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 23-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

### **%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

### **%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>3</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

---

2. <http://diveintohtml5.info/forms.html>

3. <https://secure.php.net/manual/en/function.trim.php>

## Chapter 24

# ChoiceType Field (select drop-downs, radio buttons & checkboxes)

A multi-purpose field used to allow the user to "choose" one or more options. It can be rendered as a **select** tag, radio buttons, or checkboxes.

To use this field, you must specify *either* **choices** or **choice\_loader** option.

Rendered as	can be various tags (see below)
Options	<ul style="list-style-type: none"><li>• choices</li><li>• choice_attr</li><li>• choice_label</li><li>• choice_loader</li><li>• choice_name</li><li>• choice_translation_domain</li><li>• choice_value</li><li>• expanded</li><li>• group_by</li><li>• multiple</li><li>• placeholder</li><li>• preferred_choices</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li><li>• empty_data</li><li>• error_bubbling</li><li>• trim</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• by_reference</li><li>• data</li></ul>

	<ul style="list-style-type: none"> <li>• disabled</li> <li>• error_mapping</li> <li>• inherit_data</li> <li>• label</li> <li>• label_attr</li> <li>• label_format</li> <li>• mapped</li> <li>• required</li> <li>• translation_domain</li> </ul>
Parent type	<i>FormType</i>
Class	<i>ChoiceType</i> <sup>1</sup>

## Example Usage

The easiest way to use this field is to specify the choices directly via the **choices** option:

Listing 24-1

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('isAttending', ChoiceType::class, array(
5     'choices' => array(
6         'Maybe' => null,
7         'Yes' => true,
8         'No' => false,
9     ),
10 ));

```

This will create a **select** drop-down like this:

**Attending?**

Maybe  
 Yes  
 No

If the user selects **No**, the form will return **false** for this field. Similarly, if the starting data for this field is **true**, then **Yes** will be auto-selected. In other words, the **value** of each item is the value you want to get/set in PHP code, while the **key** is what will be shown to the user.

## Advanced Example (with Objects!)

This field has a *lot* of options and most control how the field is displayed. In this example, the underlying data is some **Category** object that has a **getName()** method:

Listing 24-2

```

1 use App\Entity\Category;
2 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
3 // ...
4
5 $builder->add('category', ChoiceType::class, [
6     'choices' => [
7         new Category('Cat1'),

```

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/ChoiceType.html>

```

8     new Category('Cat2'),
9     new Category('Cat3'),
10    new Category('Cat4'),
11  ],
12  'choice_label' => function($category, $key, $index) {
13    /** @var Category $category */
14    return strtoupper($category->getName());
15  },
16  'choice_attr' => function($category, $key, $index) {
17    return ['class' => 'category_'.strtolower($category->getName())];
18  },
19
20  'group_by' => function($category, $key, $index) {
21    // randomly assign things into 2 groups
22    return rand(0, 1) == 1 ? 'Group A' : 'Group B';
23  },
24  'preferred_choices' => function($category, $key, $index) {
25    return $category->getName() == 'Cat2' || $category->getName() == 'Cat3';
26  },
27  ]);

```

You can also customize the `choice_name` and `choice_value` of each choice if you need further HTML customization.

## Select Tag, Checkboxes or Radio Buttons

This field may be rendered as one of several different HTML fields, depending on the **expanded** and **multiple** options:

Element Type	Expanded	Multiple
select tag	false	false
select tag (with <code>multiple</code> attribute)	false	true
radio buttons	true	false
checkboxes	true	true

## Customizing each Option's Text (Label)

Normally, the array key of each item in the `choices` option is used as the text that's shown to the user. But that can be completely customized via the `choice_label` option. Check it out for more details.

## Grouping Options

You can easily "group" options in a select by passing a multi-dimensional choices array:

```

Listing 24-3 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('stockStatus', ChoiceType::class, array(
5   'choices' => array(
6     'Main Statuses' => array(
7       'Yes' => 'stock_yes',
8       'No' => 'stock_no',
9     ),
10    'Out of Stock Statuses' => array(

```

```

11         'Backordered' => 'stock_backordered',
12         'Discontinued' => 'stock_discontinued',
13     ),
14 ),
15 );

```

To get fancier, use the `group_by` option.

## Field Options

### choices

**type:** array **default:** array()

This is the most basic way to specify the choices that should be used by this field. The `choices` option is an array, where the array key is the item's label and the array value is the item's value:

Listing 24-4

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('inStock', ChoiceType::class, array(
5     'choices' => array('In Stock' => true, 'Out of Stock' => false),
6 ));

```

### choice\_attr

**type:** array, callable or string **default:** array()

Use this to add additional HTML attributes to each choice. This can be an array of attributes (if they are the same for each choice), a callable or a property path (just like `choice_label`).

If an array, the keys of the `choices` array must be used as keys:

Listing 24-5

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('attending', ChoiceType::class, array(
5     'choices' => array(
6         'Yes' => true,
7         'No' => false,
8         'Maybe' => null,
9     ),
10    'choice_attr' => function($val, $key, $index) {
11        // adds a class like attending_yes, attending_no, etc
12        return ['class' => 'attending_' . strtolower($key)];
13    },
14 ));

```

## choice\_label

**type:** string, callable or false **default:** null

Normally, the array key of each item in the **choices** option is used as the text that's shown to the user. The **choice\_label** option allows you to take more control:

```
Listing 24-6 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('attending', ChoiceType::class, array(
5     'choices' => array(
6         'yes' => true,
7         'no' => false,
8         'maybe' => null,
9     ),
10    'choice_label' => function ($value, $key, $index) {
11        if ($value == true) {
12            return 'Definitely!';
13        }
14        return strtoupper($key);
15    }
16    // or if you want to translate some key
17    //return 'form.choice.'.$key;
18 },
19 ));
```

This method is called for *each* choice, passing you the choice **\$value** and the **\$key** from the choices array (**\$index** is related to **choice\_value**). This will give you:

If your choice values are objects, then **choice\_label** can also be a property path. Imagine you have some **Status** class with a **getDisplayname()** method:

```
Listing 24-7 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('attending', ChoiceType::class, array(
5     'choices' => array(
6         new Status(Status::YES),
7         new Status(Status::NO),
8         new Status(Status::MAYBE),
9     ),
10    'choice_label' => 'displayName',
11 ));
```

If set to **false**, all the tag labels will be discarded for radio or checkbox inputs. You can also return **false** from the callable to discard certain labels.

## choice\_loader

**type:** *ChoiceLoaderInterface*<sup>2</sup>

The **choice\_loader** can be used to only partially load the choices in cases where a fully-loaded list is not necessary. This is only needed in advanced cases and would replace the **choices** option.

---

2. <https://api.symfony.com/4.0/Symfony/Component/Form/ChoiceList/Loader/ChoiceLoaderInterface.html>

You can use an instance of *CallbackChoiceLoader*<sup>3</sup> if you want to take advantage of lazy loading:

```
Listing 24-8 1 use Symfony\Component\Form\ChoiceList\Loader\CallbackChoiceLoader;
2 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
3 // ...
4
5 $builder->add('constants', ChoiceType::class, array(
6     'choice_loader' => new CallbackChoiceLoader(function() {
7         return StaticClass::getConstants();
8     }),
9 ));
```

This will cause the call of `StaticClass::getConstants()` to not happen if the request is redirected and if there is no pre set or submitted data. Otherwise the choice options would need to be resolved thus triggering the callback.

### choice\_name

**type:** callable or string **default:** null

Controls the internal field name of the choice. You normally don't care about this, but in some advanced cases, you might. For example, this "name" becomes the index of the choice views in the template.

This can be a callable or a property path. See `choice_label` for similar usage. If `null` is used, an incrementing integer is used as the name.

### choice\_translation\_domain

**type:** string, boolean or null

This option determines if the choice values should be translated and in which translation domain.

The values of the `choice_translation_domain` option can be `true` (reuse the current translation domain), `false` (disable translation), `null` (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

### choice\_value

**type:** callable or string **default:** null

Returns the string "value" for each choice, which must be unique across all choices. This is used in the `value` attribute in HTML and submitted in the POST/PUT requests. You don't normally need to worry about this, but it might be handy when processing an API request (since you can configure the value that will be sent in the API request).

This can be a callable or a property path. If `null` is given, an incrementing integer is used as the value.

If you pass a callable, it will receive one argument: the choice itself. When using the *EntityType Field*, the argument will be the entity object for each choice or `null` in some cases, which you need to handle:

```
Listing 24-9 'choice_value' => function (MyOptionEntity $entity = null) {
    return $entity ? $entity->getId() : '';
},
```

### expanded

**type:** boolean **default:** false

---

3. <https://api.symfony.com/4.0/Symfony/Component/Form/ChoiceList/Loader/CallbackChoiceLoader.html>

If set to true, radio buttons or checkboxes will be rendered (depending on the **multiple** value). If false, a select element will be rendered.

## group\_by

**type:** array, callable or string **default:** null

You can easily "group" options in a select simply by passing a multi-dimensional array to **choices**. See the Grouping Options section about that.

The **group\_by** option is an alternative way to group choices, which gives you a bit more flexibility.

Take the following example:

```
Listing 24-10 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'group_by' => function($value, $key, $index) {
12        if ($value <= new \DateTime('+3 days')) {
13            return 'Soon';
14        } else {
15            return 'Later';
16        }
17    },
18 ));
```

This groups the dates that are within 3 days into "Soon" and everything else into a "Later" group:

If you return **null**, the option won't be grouped. You can also pass a string "property path" that will be called to get the group. See the `choice_label` for details about using a property path.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the **expanded** option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the **multiple** option is set to false.

- Add an empty value with "Choose an option" as the text:

```
Listing 24-11 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));
```

- Guarantee that no "empty" value option is displayed:

```
Listing 24-12 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));
```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

```
Listing 24-13 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));
```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

```
Listing 24-14 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11     'preferred_choices' => array('muppets', 'arr'),
12 ));
```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

```
Listing 24-15 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11     'preferred_choices' => function ($value, $key) {
```

```

12     // prefer options within 3 days
13     return $value <= new \DateTime('+3 days');
14 },
15 );

```

This will "prefer" the "now" and "tomorrow" choices only:

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

Listing 24-16 `1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}`

## Overridden Options

### compound

**type:** **boolean** **default:** same value as **expanded** option

This option specifies if a form is compound. The value is by default overridden by the value of the **expanded** option.

### empty\_data

**type:** **mixed**

The actual default value of this option depends on other field options:

- If **multiple** is **false** and **expanded** is **false**, then '' (empty string);
- Otherwise **array()** (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

Listing 24-17 `$builder->add('name', null, array(
 'required' => false,
 'empty_data' => 'John Doe',
));`

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false

Set that error on this field must be attached to the field instead of the parent field (the form in most cases).

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

## Inherited Options

These options inherit from the *FormType*:

### attr

**type:** array **default:** array()

If you want to add extra attributes to an HTML field representation you can use the **attr** option. It's an associative array with HTML attributes as keys. This can be useful when you need to set a custom class for some widget:

```
Listing 24-18 $builder->add('body', TextareaType::class, array(
    'attr' => array('class' => 'tinymce'),
));
```

### by\_reference

**type:** boolean **default:** true

In most cases, if you have an **author** field, then you expect **setAuthor()** to be called on the underlying object. In some cases, however, **setAuthor()** may *not* be called. Setting **by\_reference** to **false** ensures that the setter is called in all cases.

To explain this further, here's a simple example:

```
Listing 24-19 1 use Symfony\Component\Form\Extension\Core\Type\TextType;
2 use Symfony\Component\Form\Extension\Core\Type\EmailType;
3 use Symfony\Component\Form\Extension\Core\Type\FormType;
4 // ...
5
6 $builder = $this->createFormBuilder($article);
```

```

7 $builder
8     ->add('title', TextType::class)
9     ->add(
10         $builder->create('author', FormType::class, array('by_reference' => ?))
11         ->add('name', TextType::class)
12         ->add('email', EmailType::class)
13     )

```

If `by_reference` is true, the following takes place behind the scenes when you call `submit()` (or `handleRequest()`) on the form:

Listing 24-20

```

$article->setTitle('...');
$article->getAuthor()->setName('...');
$article->getAuthor()->setEmail('...');

```

Notice that `setAuthor()` is not called. The author is modified by reference.

If you set `by_reference` to false, submitting looks like this:

Listing 24-21

```

1 $article->setTitle('...');
2 $author = clone $article->getAuthor();
3 $author->setName('...');
4 $author->setEmail('...');
5 $article->setAuthor($author);

```

So, all that `by_reference=false` really does is force the framework to call the setter on the parent object.

Similarly, if you're using the `CollectionType` field where your underlying collection data is an object (like with Doctrine's `ArrayCollection`), then `by_reference` must be set to `false` if you need the adder and remover (e.g. `addAuthor()` and `removeAuthor()`) to be called.

## data

**type: mixed default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 24-22

```

1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));

```

The `data` option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type: boolean default: false**

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 24-23 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 24-24 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the `inherit_data` option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 24-25 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 24-26 1 {{ form_label(form.name, 'Your name', {  
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3         }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 24-27 1 // ...  
2 $profileFormBuilder->add('address', AddressType::class, array(  
3     'label_format' => 'form.address.%name%',  
4 ));  
5  
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(  
7     'label_format' => 'form.address.%name%',  
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** `boolean` **default:** `true`

If true, an *HTML5 required attribute*<sup>4</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## translation\_domain

**type:** `string` **default:** `messages`

In case `choice_translation_domain` is set to `true` or `null`, this configures the exact translation domain that will be used for any labels or options that are rendered for this field

## Field Variables

Variable	Type	Usage
<code>multiple</code>	<code>boolean</code>	The value of the <code>multiple</code> option.
<code>expanded</code>	<code>boolean</code>	The value of the <code>expanded</code> option.
<code>preferred_choices</code>	<code>array</code>	A nested array containing the <code>ChoiceView</code> objects of choices which should be presented to the user with priority.
<code>choices</code>	<code>array</code>	A nested array containing the <code>ChoiceView</code> objects of the remaining choices.
<code>separator</code>	<code>string</code>	The separator to use between choice groups.
<code>placeholder</code>	<code>mixed</code>	The empty value if not already in the list, otherwise <code>null</code> .
<code>choice_translation_domain</code>	<code>mixed</code>	<code>boolean</code> , <code>null</code> or <code>string</code> to determine if the value should be translated.
<code>is_selected</code>	<code>callable</code>	A callable which takes a <code>ChoiceView</code> and the selected value(s) and returns whether the choice is in the selected value(s).
<code>placeholder_in_choices</code>	<code>boolean</code>	Whether the empty value is in the choice list.

It's significantly faster to use the `selectedchoice(selected_value)` test instead when using Twig.

4. <http://diveintohtml5.info/forms.html>

## Chapter 25

# EntityType Field

A special **ChoiceType** field that's designed to load options from a Doctrine entity. For example, if you have a **Category** entity, you could use this field to display a **select** field of all, or some, of the **Category** objects from the database.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)
Options	<ul style="list-style-type: none"><li>• choice_label</li><li>• class</li><li>• em</li><li>• query_builder</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• choice_name</li><li>• choice_value</li><li>• choices</li><li>• data_class</li></ul>
Inherited options	<p>from the <i>ChoiceType</i>:</p> <ul style="list-style-type: none"><li>• choice_attr</li><li>• choice_translation_domain</li><li>• expanded</li><li>• group_by</li><li>• multiple</li><li>• placeholder</li><li>• preferred_choices</li><li>• translation_domain</li><li>• trim</li></ul> <p>from the <i>FormType</i>:</p> <ul style="list-style-type: none"><li>• data</li><li>• disabled</li></ul>

	<ul style="list-style-type: none"> <li>• empty_data</li> <li>• error_bubbling</li> <li>• error_mapping</li> <li>• label</li> <li>• label_attr</li> <li>• label_format</li> <li>• mapped</li> <li>• required</li> </ul>
Parent type	<i>ChoiceType</i>
Class	<i>EntityType</i> <sup>1</sup>

## Basic Usage

The **entity** type has just one required option: the entity which should be listed inside the choice field:

Listing 25-1

```

1 use App\Entity\User;
2 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
3 // ...
4
5 $builder->add('users', EntityType::class, array(
6     // looks for choices from this entity
7     'class' => User::class,
8
9     // uses the User.username property as the visible option string
10    'choice_label' => 'username',
11
12    // used to render a select box, check boxes or radios
13    // 'multiple' => true,
14    // 'expanded' => true,
15 ));
```

This will build a **select** drop-down containing *all* of the **User** objects in the database. To render radio buttons or checkboxes instead, change the multiple and expanded options.

## Using a Custom Query for the Entities

If you want to create a custom query to use when fetching the entities (e.g. you only want to return some entities, or need to order them), use the `query_builder` option:

Listing 25-2

```

1 use App\Entity\User;
2 use Doctrine\ORM\EntityRepository;
3 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
4 // ...
5
6 $builder->add('users', EntityType::class, array(
7     'class' => User::class,
8     'query_builder' => function (EntityRepository $er) {
9         return $er->createQueryBuilder('u')
10            ->orderBy('u.username', 'ASC');
11     },
12    'choice_label' => 'username',
13 ));
```

1. <https://api.symfony.com/4.0/Symfony/Bridge/Doctrine/Form/Type/EntityType.html>

## Using Choices

If you already have the exact collection of entities that you want to include in the choice element, just pass them via the **choices** key.

For example, if you have a **\$group** variable (passed into your form perhaps as a form option) and **getUsers()** returns a collection of **User** entities, then you can supply the **choices** option directly:

```
Listing 25-3 1 use App\Entity\User;
2 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
3 // ...
4
5 $builder->add('users', EntityType::class, array(
6     'class' => User::class,
7     'choices' => $group->getUsers(),
8 ));
```

## Select Tag, Checkboxes or Radio Buttons

This field may be rendered as one of several different HTML fields, depending on the **expanded** and **multiple** options:

Element Type	Expanded	Multiple
select tag	false	false
select tag (with multiple attribute)	false	true
radio buttons	true	false
checkboxes	true	true

## Field Options

### choice\_label

**type:** string, callable or *PropertyPath*<sup>2</sup>

This is the property that should be used for displaying the entities as text in the HTML element:

```
Listing 25-4 1 use App\Entity\Category;
2 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
3 // ...
4
5 $builder->add('category', EntityType::class, array(
6     'class' => Category::class,
7     'choice_label' => 'displayName',
8 ));
```

If left blank, the entity object will be cast to a string and so must have a **\_\_toString()** method. You can also pass a callback function for more control:

```
Listing 25-5 1 use App\Entity\Category;
2 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
3 // ...
4
```

---

2. <https://api.symfony.com/4.0/Symfony/Component/PropertyAccess/PropertyPath.html>

```

5 $builder->add('category', EntityType::class, array(
6     'class' => Category::class,
7     'choice_label' => function ($category) {
8         return $category->getDisplayName();
9     }
10 ));

```

The method is called for each entity in the list and passed to the function. For more details, see the main `choice_label` documentation.

When passing a string, the `choice_label` option is a property path. So you can use anything supported by the *PropertyAccessor component*

For example, if the translations property is actually an associative array of objects, each with a name property, then you could do this:

Listing 25-6

```

1 use Symfony\Bridge\Doctrine\Form\Type\EntityType;
2 // ...
3
4 $builder->add('genre', EntityType::class, array(
5     'class' => 'App\Entity\Genre',
6     'choice_label' => 'translations[en].name',
7 ));

```

**class**

**type: string required**

The class of your entity (e.g. `App:Category`). This can be a fully-qualified class name (e.g. `App\Entity\Category`) or the short alias name (as shown prior).

**em**

**type: string | Doctrine\Common\Persistence\ObjectManager default:** the default entity manager

If specified, this entity manager will be used to load the choices instead of the **default** entity manager.

**query\_builder**

**type: Doctrine\ORM\QueryBuilder or a callable default:** null

Allows you to create a custom query for your choices. See Using a Custom Query for the Entities for an example.

The value of this option can either be a `QueryBuilder` object, a callable or `null` (which will load all entities). When using a callable, you will be passed the `EntityRepository` of the entity as the only argument and should return a `QueryBuilder`. Returning `null` in the Closure will result in loading all entities.

The entity used in the **FROM** clause of the `query_builder` option will always be validated against the class which you have specified with the form's `class` option. If you return another entity instead of the one used in your **FROM** clause (for instance if you return an entity from a joined table), it will break validation.

## Overridden Options

### choice\_name

**type:** callable or string **default:** null

Controls the internal field name of the choice. You normally don't care about this, but in some advanced cases, you might. For example, this "name" becomes the index of the choice views in the template.

This can be a callable or a property path. See `choice_label` for similar usage. If `null` is used, an incrementing integer is used as the name.

In the `EntityType`, this defaults to the `id` of the entity, if it can be read. Otherwise, it falls back to using auto-incrementing integers.

### choice\_value

**type:** callable or string **default:** null

Returns the string "value" for each choice, which must be unique across all choices. This is used in the `value` attribute in HTML and submitted in the POST/PUT requests. You don't normally need to worry about this, but it might be handy when processing an API request (since you can configure the value that will be sent in the API request).

This can be a callable or a property path. If `null` is given, an incrementing integer is used as the value.

If you pass a callable, it will receive one argument: the choice itself. When using the `EntityType Field`, the argument will be the entity object for each choice or `null` in some cases, which you need to handle:

```
Listing 25-7 'choice_value' => function (MyOptionEntity $entity = null) {  
    return $entity ? $entity->getId() : '';  
},
```

In the `EntityType`, this is overridden to use the `id` by default. When the `id` is used, Doctrine only queries for the objects for the ids that were actually submitted.

### choices

**type:** array | \Traversable **default:** null

Instead of allowing the `class` and `query_builder` options to fetch the entities to include for you, you can pass the `choices` option directly. See [Using Choices](#).

### data\_class

**type:** string **default:** null

This option is not used in favor of the `class` option which is required to query the entities.

## Inherited Options

These options inherit from the `ChoiceType`:

### choice\_attr

**type:** array, callable or string **default:** array()

Use this to add additional HTML attributes to each choice. This can be an array of attributes (if they are the same for each choice), a callable or a property path (just like `choice_label`).

If an array, the keys of the `choices` array must be used as keys:

```
Listing 25-8 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('attending', ChoiceType::class, array(
5     'choices' => array(
6         'Yes' => true,
7         'No' => false,
8         'Maybe' => null,
9     ),
10    'choice_attr' => function($val, $key, $index) {
11        // adds a class like attending_yes, attending_no, etc
12        return ['class' => 'attending_' . strtolower($key)];
13    },
14 ));
```

## choice\_translation\_domain

**type:** string, boolean or null

This option determines if the choice values should be translated and in which translation domain.

The values of the `choice_translation_domain` option can be **true** (reuse the current translation domain), **false** (disable translation), **null** (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

## expanded

**type:** boolean **default:** false

If set to true, radio buttons or checkboxes will be rendered (depending on the `multiple` value). If false, a select element will be rendered.

## group\_by

**type:** array, callable or string **default:** null

You can easily "group" options in a select simply by passing a multi-dimensional array to `choices`. See the Grouping Options section about that.

The `group_by` option is an alternative way to group choices, which gives you a bit more flexibility.

Take the following example:

```
Listing 25-9 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'group_by' => function($value, $key, $index) {
12        if ($value <= new \DateTime('+3 days')) {
13            return 'Soon';
14        } else {
15            return 'Later';
16        }
17    }
18 ));
```

```
17     },  
18 });
```

This groups the dates that are within 3 days into "Soon" and everything else into a "Later" group:

If you return `null`, the option won't be grouped. You can also pass a string "property path" that will be called to get the group. See the `choice_label` for details about using a property path.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the `expanded` option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

If you are working with a collection of Doctrine entities, it will be helpful to read the documentation for the *CollectionType Field* as well. In addition, there is a complete example in the *How to Embed a Collection of Forms* article.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the `multiple` option is set to false.

- Add an empty value with "Choose an option" as the text:

```
Listing 25-10 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;  
2 // ...  
3  
4 $builder->add('states', ChoiceType::class, array(  
5     'placeholder' => 'Choose an option',  
6 ));
```

- Guarantee that no "empty" value option is displayed:

```
Listing 25-11 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;  
2 // ...  
3  
4 $builder->add('states', ChoiceType::class, array(  
5     'placeholder' => false,  
6 ));
```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

Listing 25-12

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));

```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

Listing 25-13

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));

```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

Listing 25-14

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');
14    },
15 ));

```

This will "prefer" the "now" and "tomorrow" choices only:

The image shows a form field with the label "Publish at". A dropdown menu is open, displaying four options: "now" (with a checkmark), "tomorrow", "1 week", and "1 month". A horizontal dashed line is positioned between "tomorrow" and "1 week".

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

```
Listing 25-15 1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}
```

This option expects an array of entity objects (that's actually the same as with the **ChoiceType** field, which requires an array of the preferred "values").

## translation\_domain

**type:** string **default:** messages

In case `choice_translation_domain` is set to **true** or **null**, this configures the exact translation domain that will be used for any labels or options that are rendered for this field

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *form* type:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the `data` option:

```
Listing 25-16 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the `disabled` option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is `false` and `expanded` is `false`, then `''` (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 25-17 $builder->add('name', null, array(  
    'required' => false,  
    'empty_data' => 'John Doe',  
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 25-18 1 public function configureOptions(OptionsResolver $resolver)  
2 {  
3     $resolver->setDefaults(array(  
4         'error_mapping' => array(  
5             'matchingCityAndZipCode' => 'city',  
6         ),  
7     ));  
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 25-19 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 25-20 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 25-21 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 25-22 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
```

```
7     'label_format' => 'form.address.%name%',  
8 );
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

3. <http://diveintohtml5.info/forms.html>

## Chapter 26

# CountryType Field

The **CountryType** is a subset of the **ChoiceType** that displays countries of the world. As an added bonus, the country names are displayed in the language of the user.

The "value" for each country is the two-letter country code.

The locale of your user is guessed using `Locale::getDefault()`<sup>1</sup>

Unlike the **ChoiceType**, you don't need to specify a **choices** option as the field type automatically uses all of the countries of the world. You *can* specify the option manually, but then you should just use the **ChoiceType** directly.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)
Overridden options	<ul style="list-style-type: none"><li>choices</li></ul>
Inherited options	<p>from the <i>ChoiceType</i></p> <ul style="list-style-type: none"><li>error_bubbling</li><li>error_mapping</li><li>expanded</li><li>multiple</li><li>placeholder</li><li>preferred_choices</li><li>trim</li></ul> <p>from the <i>FormType</i></p> <ul style="list-style-type: none"><li>data</li><li>disabled</li></ul>

1. <https://secure.php.net/manual/en/locale.getdefault.php>

	<ul style="list-style-type: none"> <li>• empty_data</li> <li>• label</li> <li>• label_attr</li> <li>• label_format</li> <li>• mapped</li> <li>• required</li> </ul>
Parent type	<i>ChoiceType</i>
Class	<i>CountryType<sup>2</sup></i>

## Overridden Options

### choices

**default:** `Symfony\Component\Intl\Intl::getRegionBundle()->getCountryNames()`

The country type defaults the **choices** option to the whole list of countries. The locale is used to translate the countries names.

If you want to override the built-in choices of the country type, you will also have to set the **choice\_loader** option to **null**.

## Inherited Options

These options inherit from the *ChoiceType*:

### error\_bubbling

**type:** boolean **default:** `false` unless the form is **compound**

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

### error\_mapping

**type:** array **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

Listing 26-1

```

1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
```

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/CountryType.html>

```

4     'error_mapping' => array(
5         'matchingCityAndZipCode' => 'city',
6     ),
7 );
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an `array` or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

Listing 26-2

```

1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));

```

## expanded

**type:** boolean **default:** false

If set to true, radio buttons or checkboxes will be rendered (depending on the `multiple` value). If false, a select element will be rendered.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the `expanded` option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the `multiple` option is set to false.

- Add an empty value with "Choose an option" as the text:

Listing 26-3

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));

```

- Guarantee that no "empty" value option is displayed:

```
Listing 26-4 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));
```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

```
Listing 26-5 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));
```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

```
Listing 26-6 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));
```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

```
Listing 26-7 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');
14    },
15 ));
```

This will "prefer" the "now" and "tomorrow" choices only:

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

Listing 26-8 

```
1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}
```

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 26-9 

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is `false` and `expanded` is `false`, then '' (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 26-10 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to `false` will suppress the label. The label can also be directly set inside the template:

```
Listing 26-11 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 26-12 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 26-13 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type: boolean default: true**

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default: true**

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

## Chapter 27

# LanguageType Field

The **LanguageType** is a subset of the **ChoiceType** that allows the user to select from a large list of languages. As an added bonus, the language names are displayed in the language of the user.

The "value" for each language is the *Unicode language identifier* used in the *International Components for Unicode*<sup>1</sup> (e.g. `fr` or `zh_Hant`).

The locale of your user is guessed using `Locale::getDefault()`<sup>2</sup>, which requires the `intl` PHP extension to be installed and enabled.

Unlike the **ChoiceType**, you don't need to specify a `choices` option as the field type automatically uses a large list of languages. You *can* specify the option manually, but then you should just use the **ChoiceType** directly.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)

1. <http://site.icu-project.org>

2. <https://secure.php.net/manual/en/locale.getdefault.php>

	<ul style="list-style-type: none"> <li>• data</li> <li>• disabled</li> <li>• empty_data</li> <li>• label</li> <li>• label_attr</li> <li>• label_format</li> <li>• mapped</li> <li>• required</li> </ul>
Parent type	<i>ChoiceType</i>
Class	<i>LanguageType</i> <sup>3</sup>

## Overridden Options

### choices

**default:** `Symfony\Component\Intl\Intl::getLanguageBundle()->getLanguageNames()`.

The choices option defaults to all languages. The default locale is used to translate the languages names.

If you want to override the built-in choices of the language type, you will also have to set the `choice_loader` option to `null`.

## Inherited Options

These options inherit from the *ChoiceType*:

### error\_bubbling

**type:** boolean **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

### error\_mapping

**type:** array **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

Listing 27-1

```

1 public function configureOptions(OptionsResolver $resolver)
2 {

```

3. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/LanguageType.html>

```

3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

Listing 27-2

```

1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));

```

## expanded

**type:** boolean **default:** false

If set to true, radio buttons or checkboxes will be rendered (depending on the `multiple` value). If false, a select element will be rendered.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the `expanded` option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the `multiple` option is set to false.

- Add an empty value with "Choose an option" as the text:

Listing 27-3

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));

```

- Guarantee that no "empty" value option is displayed:

```
Listing 27-4 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));
```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

```
Listing 27-5 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));
```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

```
Listing 27-6 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));
```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

```
Listing 27-7 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');
14    },
15 ));
```

This will "prefer" the "now" and "tomorrow" choices only:

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

Listing 27-8 

```
1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}
```

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 27-9 

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is `false` and `expanded` is `false`, then '' (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 27-10 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to `false` will suppress the label. The label can also be directly set inside the template:

```
Listing 27-11 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 27-12 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 27-13 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type: boolean default: true**

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default: true**

If true, an *HTML5 required attribute*<sup>4</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

4. <http://diveintohtml5.info/forms.html>

## Chapter 28

# LocaleType Field

The **LocaleType** is a subset of the **ChoiceType** that allows the user to select from a large list of locales (language+country). As an added bonus, the locale names are displayed in the language of the user.

The "value" for each locale is either the two letter *ISO 639-1*<sup>1</sup> *language* code (e.g. **fr**), or the language code followed by an underscore (**\_**), then the *ISO 3166-1*<sup>2</sup> *alpha-2* *country* code (e.g. **fr\_FR** for French/France).

The locale of your user is guessed using `Locale::getDefault()`<sup>3</sup>

Unlike the **ChoiceType**, you don't need to specify a **choices** option as the field type automatically uses a large list of locales. You *can* specify these options manually, but then you should just use the **ChoiceType** directly.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)

Parent type	<i>ChoiceType</i>
Class	<i>LocaleType</i> <sup>4</sup>

## Overridden Options

### choices

**default:** `Symfony\Component\Intl\Intl::getLocaleBundle()->getLocaleNames()`

The choices option defaults to all locales. It uses the default locale to specify the language.

If you want to override the built-in choices of the locale type, you will also have to set the `choice_loader` option to `null`.

## Inherited Options

These options inherit from the *ChoiceType*:

### error\_bubbling

**type:** boolean **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

### error\_mapping

**type:** array **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

Listing 28-1

```

1 public function configureOptions(OptionsResolver $resolver)
2 {

```

4. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/LocaleType.html>

```

3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

Listing 28-2

```

1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));

```

## expanded

**type:** boolean **default:** false

If set to true, radio buttons or checkboxes will be rendered (depending on the `multiple` value). If false, a select element will be rendered.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the `expanded` option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the `multiple` option is set to false.

- Add an empty value with "Choose an option" as the text:

Listing 28-3

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));

```

- Guarantee that no "empty" value option is displayed:

```
Listing 28-4 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));
```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

```
Listing 28-5 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));
```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

```
Listing 28-6 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));
```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

```
Listing 28-7 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');
14    },
15 ));
```

This will "prefer" the "now" and "tomorrow" choices only:

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

Listing 28-8 

```
1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}
```

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 28-9 

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is `false` and `expanded` is `false`, then '' (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 28-10 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to `false` will suppress the label. The label can also be directly set inside the template:

```
Listing 28-11 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 28-12 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is built for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 28-13 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type: boolean default: true**

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default: true**

If true, an *HTML5 required attribute*<sup>5</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

5. <http://diveintohtml5.info/forms.html>

## Chapter 29

# TimezoneType Field

The **TimezoneType** is a subset of the **ChoiceType** that allows the user to select from all possible timezones.

The "value" for each timezone is the full timezone name, such as **America/Chicago** or **Europe/Istanbul**.

Unlike the **ChoiceType**, you don't need to specify a **choices** option as the field type automatically uses a large list of timezones. You *can* specify the option manually, but then you should just use the **ChoiceType** directly.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)
Options	<ul style="list-style-type: none"><li>• input</li><li>• regions</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• choices</li></ul>
Inherited options	<p>from the <i>ChoiceType</i></p> <ul style="list-style-type: none"><li>• expanded</li><li>• multiple</li><li>• placeholder</li><li>• preferred_choices</li><li>• trim</li></ul> <p>from the <i>FormType</i></p> <ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li></ul>

	<ul style="list-style-type: none"> <li>• label_attr</li> <li>• label_format</li> <li>• mapped</li> <li>• required</li> </ul>
Parent type	<i>ChoiceType</i>
Class	<i>TimezoneType</i> <sup>1</sup>

## Field Options

### input

**type:** string **default:** string

The format of the *input* data - i.e. the format that the timezone is stored on your underlying object. Valid values are:

- string (e.g. America/New\_York)
- datetimestzone (a `DateTimeZone` object)

### regions

**type:** int **default:** `\DateTimeZone::ALL`

The available regions in the timezone choice list. For example: `DateTimeZone::AMERICA` | `DateTimeZone::EUROPE`

## Overridden Options

### choices

**default:** An array of timezones.

The `Timezone` type defaults the choices to all timezones returned by `DateTimeZone::listIdentifiers()`<sup>2</sup>, broken down by continent.

If you want to override the built-in choices of the timezone type, you will also have to set the `choice_loader` option to `null`.

## Inherited Options

These options inherit from the *ChoiceType*:

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/TimezoneType.html>  
2. <https://secure.php.net/manual/en/datetimezone.listidentifiers.php>

## expanded

**type:** boolean **default:** false

If set to true, radio buttons or checkboxes will be rendered (depending on the **multiple** value). If false, a select element will be rendered.

## multiple

**type:** boolean **default:** false

If true, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the **expanded** option, this will render either a select tag or checkboxes if true and a select tag or radio buttons if false. The returned value will be an array.

## placeholder

**type:** string or boolean

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the **multiple** option is set to false.

- Add an empty value with "Choose an option" as the text:

```
Listing 29-1 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));
```

- Guarantee that no "empty" value option is displayed:

```
Listing 29-2 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));
```

If you leave the **placeholder** option unset, then a blank (with no text) option will automatically be added if and only if the **required** option is false:

```
Listing 29-3 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));
```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

Listing 29-4

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));

```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

```

Listing 29-5 1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');
14    },
15 ));

```

This will "prefer" the "now" and "tomorrow" choices only:

**Publish at**

- ✓ now
- tomorrow
- 
- 1 week
- 1 month

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

```

Listing 29-6 1 {{ form_widget(form.publishAt, { 'separator': '=====' }) }}

```

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 29-7 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is false and `expanded` is false, then '' (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 29-8 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

Form data transformers will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 29-9 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 29-10 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** `string` **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 29-11 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 29-12 1 {{ form_label(form.name, 'Your name', {  
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3         }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 29-13 1 // ...  
2 $profileFormBuilder->add('address', AddressType::class, array(  
3     'label_format' => 'form.address.%name%',  
4 ));  
5  
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(  
7     'label_format' => 'form.address.%name%',  
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

---

3. <http://diveintohtml5.info/forms.html>

## Chapter 30

# CurrencyType Field

The **CurrencyType** is a subset of the *ChoiceType* that allows the user to select from a large list of 3-letter ISO 4217<sup>1</sup> currencies.

Unlike the **ChoiceType**, you don't need to specify a **choices** option as the field type automatically uses a large list of currencies. You *can* specify the option manually, but then you should just use the **ChoiceType** directly.

Rendered as	can be various tags (see Select Tag, Checkboxes or Radio Buttons)
Overridden options	<ul style="list-style-type: none"><li>• choices</li></ul>
Inherited options	<p>from the <i>ChoiceType</i></p> <ul style="list-style-type: none"><li>• error_bubbling</li><li>• expanded</li><li>• multiple</li><li>• placeholder</li><li>• preferred_choices</li><li>• trim</li></ul> <p>from the <i>FormType</i> type</p> <ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>ChoiceType</i>

1. [https://en.wikipedia.org/wiki/ISO\\_4217](https://en.wikipedia.org/wiki/ISO_4217)

## Overridden Options

### choices

**default:** `Symfony\Component\Intl\Intl::getCurrencyBundle()->getCurrencyNames()`

The choices option defaults to all currencies.

If you want to override the built-in choices of the currency type, you will also have to set the `choice_loader` option to `null`.

## Inherited Options

These options inherit from the *ChoiceType*:

### error\_bubbling

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

### expanded

**type:** `boolean` **default:** `false`

If set to `true`, radio buttons or checkboxes will be rendered (depending on the `multiple` value). If `false`, a select element will be rendered.

### multiple

**type:** `boolean` **default:** `false`

If `true`, the user will be able to select multiple options (as opposed to choosing just one option). Depending on the value of the `expanded` option, this will render either a select tag or checkboxes if `true` and a select tag or radio buttons if `false`. The returned value will be an array.

### placeholder

**type:** `string` or `boolean`

This option determines whether or not a special "empty" option (e.g. "Choose an option") will appear at the top of a select widget. This option only applies if the `multiple` option is set to `false`.

- Add an empty value with "Choose an option" as the text:

Listing 30-1 

```
1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
```

---

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/CurrencyType.html>

```

3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => 'Choose an option',
6 ));

```

- Guarantee that no "empty" value option is displayed:

Listing 30-2

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('states', ChoiceType::class, array(
5     'placeholder' => false,
6 ));

```

If you leave the `placeholder` option unset, then a blank (with no text) option will automatically be added if and only if the `required` option is false:

Listing 30-3

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 // a blank (with no text) option will be added
5 $builder->add('states', ChoiceType::class, array(
6     'required' => false,
7 ));

```

## preferred\_choices

**type:** array, callable or string **default:** array()

This option allows you to move certain choices to the top of your list with a visual separator between them and the rest of the options. If you have a form of languages, you can list the most popular on top, like Bork Bork and Pirate:

Listing 30-4

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('language', ChoiceType::class, array(
5     'choices' => array(
6         'English' => 'en',
7         'Spanish' => 'es',
8         'Bork' => 'muppets',
9         'Pirate' => 'arr',
10    ),
11    'preferred_choices' => array('muppets', 'arr'),
12 ));

```

This options can also be a callback function to give you more flexibility. This might be especially useful if your values are objects:

Listing 30-5

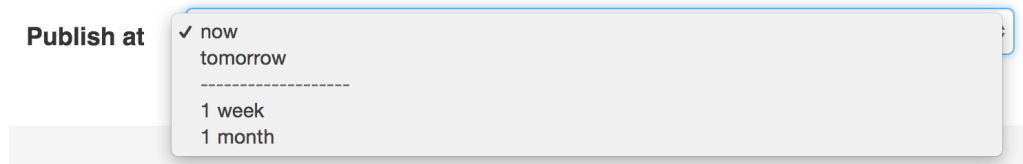

```

1 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
2 // ...
3
4 $builder->add('publishAt', ChoiceType::class, array(
5     'choices' => array(
6         'now' => new \DateTime('now'),
7         'tomorrow' => new \DateTime('+1 day'),
8         '1 week' => new \DateTime('+1 week'),
9         '1 month' => new \DateTime('+1 month'),
10    ),
11    'preferred_choices' => function ($value, $key) {
12        // prefer options within 3 days
13        return $value <= new \DateTime('+3 days');

```

```
14     },
15  });
```

This will "prefer" the "now" and "tomorrow" choices only:

**Publish at**

- ✓ now
- tomorrow
- 
- 1 week
- 1 month

Finally, if your values are objects, you can also specify a property path string on the object that will return true or false.

The preferred choices are only meaningful when rendering a **select** element (i.e. **expanded** false). The preferred choices and normal choices are separated visually by a set of dotted lines (i.e. -----). This can be customized when rendering the field:

Listing 30-6 

```
1 {{ form_widget(form.publishAt, { 'separator': '====' }) }}
```

## trim

**type:** boolean **default:** false

Trimming is disabled by default because the selected value or values must match the given choice values exactly (and they could contain whitespaces).

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 30-7 

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## empty\_data

**type:** mixed

The actual default value of this option depends on other field options:

- If `multiple` is `false` and `expanded` is `false`, then `''` (empty string);
- Otherwise `array()` (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the `name` field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 30-8 $builder->add('name', null, array(  
    'required' => false,  
    'empty_data' => 'John Doe',  
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the `data` or `placeholder` options to show this initial value in the rendered form.

If a form is compound, you can set `empty_data` as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the `empty_data` option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the `empty_data` value. This means that an empty string will be cast to `null`. Use a custom data transformer if you explicitly want to return the empty string.

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to `false` will suppress the label. The label can also be directly set inside the template:

```
Listing 30-9 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 30-10 1 {{ form_label(form.name, 'Your name', {  
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3         }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 30-11 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>3</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

---

3. <http://diveintohtml5.info/forms.html>

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Chapter 31

# DateType Field

A field that allows the user to modify date information via a variety of different HTML elements.

This field can be rendered in a variety of different ways via the `widget` option and can understand a number of different input formats via the `input` option.

Underlying Data Type	can be <code>DateTime</code> , <code>string</code> , <code>timestamp</code> , or <code>array</code> (see the <code>input</code> option)
Rendered as	single text box or three select fields
Options	<ul style="list-style-type: none"><li>• <code>choice_translation_domain</code></li><li>• <code>days</code></li><li>• <code>placeholder</code></li><li>• <code>format</code></li><li>• <code>html5</code></li><li>• <code>input</code></li><li>• <code>model_timezone</code></li><li>• <code>months</code></li><li>• <code>view_timezone</code></li><li>• <code>widget</code></li><li>• <code>years</code></li></ul>
Overridden options	<ul style="list-style-type: none"><li>• <code>by_reference</code></li><li>• <code>compound</code></li><li>• <code>data_class</code></li><li>• <code>error_bubbling</code></li></ul>
Inherited options	<ul style="list-style-type: none"><li>• <code>data</code></li><li>• <code>disabled</code></li><li>• <code>error_mapping</code></li><li>• <code>inherit_data</code></li><li>• <code>invalid_message</code></li></ul>

	<ul style="list-style-type: none"> <li>• <code>invalid_message_parameters</code></li> <li>• <code>mapped</code></li> </ul>
Parent type	<code>FormType</code>
Class	<code>DateType<sup>1</sup></code>

## Basic Usage

This field type is highly configurable, but easy to use. The most important options are `input` and `widget`.

Suppose that you have a `publishedAt` field whose underlying date is a `DateTime` object. The following configures the `date` type for that field as **three different choice fields**:

```
Listing 31-1 1 use Symfony\Component\Form\Extension\Core\Type\DateTime;
2 // ...
3
4 $builder->add('publishedAt', DateTime::class, array(
5     'widget' => 'choice',
6 ));
```

If your underlying date is *not* a `DateTime` object (e.g. it's a unix timestamp), configure the `input` option.

### Rendering a single HTML5 Textbox

For a better user experience, you may want to render a single text field and use some kind of "date picker" to help your user fill in the right format. To do that, use the `single_text` widget:

```
Listing 31-2 1 use Symfony\Component\Form\Extension\Core\Type\DateTime;
2 // ...
3
4 $builder->add('publishedAt', DateTime::class, array(
5     // renders it as a single text box
6     'widget' => 'single_text',
7 ));
```

This will render as an `input type="date"` HTML5 field, which means that **some - but not all - browsers will add nice date picker functionality to the field**. If you want to be absolutely sure that *every* user has a consistent date picker, use an external JavaScript library.

For example, suppose you want to use the *Bootstrap Datepicker*<sup>2</sup> library. First, make the following changes:

```
Listing 31-3 1 use Symfony\Component\Form\Extension\Core\Type\DateTime;
2 // ...
3
4 $builder->add('publishedAt', DateTime::class, array(
5     'widget' => 'single_text',
6
7     // prevents rendering it as type="date", to avoid HTML5 date pickers
8     'html5' => false,
9
10    // adds a class that can be selected in JavaScript
11    'attr' => ['class' => 'js-datepicker'],
12 ));
```

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/DateTime.html>

2. <https://github.com/eternicode/bootstrap-datepicker>

Then, add the following JavaScript code in your template to initialize the date picker:

```
Listing 31-4 1 <script>
2     $(document).ready(function() {
3         // you may need to change this code if you are not using Bootstrap Datpicker
4         $('<code>.js-datepicker</code>').datepicker({
5             format: 'yyyy-mm-dd'
6         });
7     });
8 </script>
```

This **format** key tells the date picker to use the date format that Symfony expects. This can be tricky: if the date picker is misconfigured, Symfony won't understand the format and will throw a validation error. You can also configure the format that Symfony should expect via the **format** option.

The string used by a JavaScript date picker to describe its format (e.g. **yyyy-mm-dd**) may not match the string that Symfony uses (e.g. **yyyy-MM-dd**). This is because different libraries use different formatting rules to describe the date format. Be aware of this - it can be tricky to make the formats truly match!

## Field Options

### choice\_translation\_domain

**type:** string, boolean or null

This option determines if the choice values should be translated and in which translation domain.

The values of the **choice\_translation\_domain** option can be **true** (reuse the current translation domain), **false** (disable translation), **null** (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

### days

**type:** array **default:** 1 to 31

List of days available to the day field type. This option is only relevant when the **widget** option is set to **choice**:

```
Listing 31-5 'days' => range(1,31)
```

### placeholder

**type:** string | array

If your widget option is set to **choice**, then this field will be represented as a series of **select** boxes. When the placeholder value is a string, it will be used as the **blank value** of all select boxes:

```
Listing 31-6 $builder->add('dueDate', DateType::class, array(
    'placeholder' => 'Select a value',
));
```

Alternatively, you can use an array that configures different placeholder values for the year, month and day fields:

```
Listing 31-7 1 $builder->add('dueDate', DateType::class, array(
2     'placeholder' => array(
```

```

3     'year' => 'Year', 'month' => 'Month', 'day' => 'Day',
4     )
5 );

```

## format

**type:** integer or string **default:** `IntlDateFormatter::MEDIUM`<sup>3</sup> (or `yyyy-MM-dd` if widget is `single_text`)

Option passed to the `IntlDateFormatter` class, used to transform user input into the proper format. This is critical when the widget option is set to `single_text` and will define how the user will input the data. By default, the format is determined based on the current user locale: meaning that *the expected format will be different for different users*. You can override it by passing the format as a string.

For more information on valid formats, see *Date/Time Format Syntax*<sup>4</sup>:

Listing 31-8

```

1 use Symfony\Component\Form\Extension\Core\Type\DateType;
2 // ...
3
4 $builder->add('date_created', DateType::class, array(
5     'widget' => 'single_text',
6     // this is actually the default format for single_text
7     'format' => 'yyyy-MM-dd',
8 ));

```

If you want your field to be rendered as an HTML5 "date" field, you have to use a `single_text` widget with the `yyyy-MM-dd` format (the *RFC 3339*<sup>5</sup> format) which is the default value if you use the `single_text` widget.

## html5

**type:** boolean **default:** true

If this is set to `true` (the default), it'll use the HTML5 type (date, time or datetime) to render the field. When set to `false`, it'll use the text type.

This is useful when you want to use a custom JavaScript datapicker, which often requires a text type instead of an HTML5 type.

## input

**type:** string **default:** datetime

The format of the *input* data - i.e. the format that the date is stored on your underlying object. Valid values are:

- string (e.g. 2011-06-05)
- datetime (a `DateTime` object)
- array (e.g. `array('year' => 2011, 'month' => 06, 'day' => 05)`)
- timestamp (e.g. 1307232000)

The value that comes back from the form will also be normalized back into this format.

3. <https://php.net/manual/en/class.intldateformatter.php#intl.intldateformatter-constants>

4. <http://userguide.icu-project.org/formatparse/datetime#TOC-Date-Time-Format-Syntax>

5. <https://tools.ietf.org/html/rfc3339>

If `timestamp` is used, `DateType` is limited to dates between Fri, 13 Dec 1901 20:45:54 GMT and Tue, 19 Jan 2038 03:14:07 GMT on 32bit systems. This is due to a *limitation in PHP itself*<sup>6</sup>.

### `model_timezone`

**type:** `string` **default:** system default timezone

Timezone that the input data is stored in. This must be one of the *PHP supported timezones*<sup>7</sup>.

### `months`

**type:** `array` **default:** 1 to 12

List of months available to the month field type. This option is only relevant when the `widget` option is set to `choice`.

### `view_timezone`

**type:** `string` **default:** system default timezone

Timezone for how the data should be shown to the user (and therefore also the data that the user submits). This must be one of the *PHP supported timezones*<sup>8</sup>.

### `widget`

**type:** `string` **default:** `choice`

The basic way in which this field should be rendered. Can be one of the following:

- `choice`: renders three select inputs. The order of the selects is defined in the format option.
- `text`: renders a three field input of type `text` (month, day, year).
- `single_text`: renders a single input of type `date`. User's input is validated based on the format option.

### `years`

**type:** `array` **default:** five years before to five years after the current year

List of years available to the year field type. This option is only relevant when the `widget` option is set to `choice`.

## Overridden Options

### `by_reference`

**default:** `false`

The `DateTime` classes are treated as immutable objects.

---

6. <https://php.net/manual/en/function.date.php#refsect1-function.date-changelog>

7. <https://php.net/manual/en/timezones.php>

8. <https://php.net/manual/en/timezones.php>

## compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

## data\_class

**type:** string **default:** null

The internal normalized representation of this type is an array, not a `\DateTime` object. Therefore, the `data_class` option is initialized to `null` to avoid the `FormType` object from initializing it to `\DateTime`.

## error\_bubbling

**default:** false

# Inherited Options

These options inherit from the `FormType`:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 31-9 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The `data` option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 31-10 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 31-11 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the `inherit_data` option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 31-12 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## Field Variables

Variable	Type	Usage
widget	mixed	The value of the widget option.
type	string	Only present when widget is <code>single_text</code> and HTML5 is activated, contains the input type to use ( <code>datetime</code> , <code>date</code> or <code>time</code> ).
date_pattern	string	A string with the date format to use.

## Chapter 32

# DateIntervalType Field

This field allows the user to select an *interval* of time. For example, if you want to allow the user to choose *how often* they receive a status email, they could use this field to choose intervals like every "10 minutes" or "3 days".

The field can be rendered in a variety of different ways (see widget) and can be configured to give you a **DateInterval** object, an *ISO 8601*<sup>1</sup> duration string (e.g. **P1DT12H**) or an array (see input).

Underlying Data Type	can be <code>DateInterval</code> , string or array (see the input option)
Rendered as	single text box, multiple text boxes or select fields - see the widget option
Options	<ul style="list-style-type: none"><li>• days</li><li>• hours</li><li>• minutes</li><li>• months</li><li>• seconds</li><li>• weeks</li><li>• input</li><li>• labels</li><li>• placeholder</li><li>• widget</li><li>• with_days</li><li>• with_hours</li><li>• with_invert</li><li>• with_minutes</li><li>• with_months</li><li>• with_seconds</li><li>• with_weeks</li><li>• with_years</li><li>• years</li></ul>

1. [https://en.wikipedia.org/wiki/ISO\\_8601](https://en.wikipedia.org/wiki/ISO_8601)

Inherited options	<ul style="list-style-type: none"> <li>• data</li> <li>• disabled</li> <li>• inherit_data</li> <li>• invalid_message</li> <li>• invalid_message_parameters</li> <li>• mapped</li> </ul>
Parent type	<i>FormType</i>
Class	<i>DateIntervalType<sup>2</sup></i>

## Basic Usage

This field type is highly configurable, but easy to use. The most important options are `input` and `widget`. You can configure *a lot* of different options, including exactly *which* range options to show (e.g. don't show "months", but *do* show "days"):

```
Listing 32-1 1 $builder->add('remindEvery', DateIntervalType::class, array(
2     'widget'      => 'integer', // render a text field for each part
3     // 'input'    => 'string', // if you want the field to return a ISO 8601 string back to you
4
5     // customize which text boxes are shown
6     'with_years' => false,
7     'with_months' => false,
8     'with_days'  => true,
9     'with_hours' => true,
10 ));
```

## Field Options

### days

**type:** array **default:** 0 to 31

List of days available to the days field type. This option is only relevant when the `widget` option is set to `choice`:

```
Listing 32-2 'days' => range(1, 31)
```

### placeholder

**type:** string or array

If your widget option is set to `choice`, then this field will be represented as a series of `select` boxes. The `placeholder` option can be used to add a "blank" entry to the top of each select box:

```
Listing 32-3 $builder->add('remindEvery', DateIntervalType::class, array(
    'placeholder' => '',
));
```

Alternatively, you can specify a string to be displayed for the "blank" value:

```
Listing 32-4
```

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/DateIntervalType.html>

```
$builder->add('remindEvery', DateIntervalType::class, array(
    'placeholder' => array('years' => 'Years', 'months' => 'Months', 'days' => 'Days')
));
```

## hours

**type:** array **default:** 0 to 24

List of hours available to the hours field type. This option is only relevant when the **widget** option is set to **choice**:

Listing 32-5 `'hours' => range(1, 24)`

## input

**type:** string **default:** dateinterval

The format of the *input* data - i.e. the format that the interval is stored on your underlying object. Valid values are:

- string (a string formatted with *ISO 8601*<sup>3</sup> standard, e.g. P7Y6M5DT12H15M30S)
- dateinterval (a DateInterval object)
- array (e.g. array('days' => '1', 'hours' => '12',))

The value that comes back from the form will also be normalized back into this format.

## labels

**type:** array **default:** (see below)

The labels displayed for each of the elements of this type. The default values are **null**, so they display the "humanized version" of the child names (**Invert**, **Years**, etc.):

Listing 32-6

```
1 'labels' => array(
2     'invert' => null,
3     'years' => null,
4     'months' => null,
5     'days' => null,
6     'hours' => null,
7     'minutes' => null,
8     'seconds' => null,
9 )
```

## minutes

**type:** array **default:** 0 to 60

List of minutes available to the minutes field type. This option is only relevant when the **widget** option is set to **choice**:

Listing 32-7 `'minutes' => range(1, 60)`

## months

**type:** array **default:** 0 to 12

List of months available to the months field type. This option is only relevant when the **widget** option is set to **choice**:

---

3. [https://en.wikipedia.org/wiki/ISO\\_8601](https://en.wikipedia.org/wiki/ISO_8601)

```
'months' => range(1, 12)
```

Listing 32-8

## seconds

**type:** array **default:** 0 to 60

List of seconds available to the seconds field type. This option is only relevant when the **widget** option is set to **choice**:

```
Listing 32-9 'seconds' => range(1, 60)
```

## weeks

**type:** array **default:** 0 to 52

List of weeks available to the weeks field type. This option is only relevant when the **widget** option is set to **choice**:

```
Listing 32-10 'weeks' => range(1, 52)
```

## widget

**type:** string **default:** choice

The basic way in which this field should be rendered. Can be one of the following:

- **choice:** renders one to six select inputs for years, months, weeks, days, hours, minutes and/or seconds, depending on the `with_years`, `with_months`, `with_weeks`, `with_days`, `with_hours`, `with_minutes` and `with_seconds` options. Default: Three fields for years, months and days.
- **text:** renders one to six text inputs for years, months, weeks, days, hours, minutes and/or seconds, depending on the `with_years`, `with_months`, `with_weeks`, `with_days`, `with_hours`, `with_minutes` and `with_seconds` options. Default: Three fields for years, months and days.
- **integer:** renders one to six integer inputs for years, months, weeks, days, hours, minutes and/or seconds, depending on the `with_years`, `with_months`, `with_weeks`, `with_days`, `with_hours`, `with_minutes` and `with_seconds` options. Default: Three fields for years, months and days.
- **single\_text:** renders a single input of type text. User's input will be validated against the form `PnYnMnDTnHnMnS` (or `PnW` if using only weeks).

## with\_days

**type:** Boolean **default:** true

Whether or not to include days in the input. This will result in an additional input to capture days.

This can not be used when `with_weeks` is enabled.

## with\_hours

**type:** Boolean **default:** false

Whether or not to include hours in the input. This will result in an additional input to capture hours.

## with\_invert

**type:** Boolean **default:** false

Whether or not to include invert in the input. This will result in an additional checkbox. This can not be used when the widget option is set to `single_text`.

#### `with_minutes`

**type:** Boolean **default:** false

Whether or not to include minutes in the input. This will result in an additional input to capture minutes.

#### `with_months`

**type:** Boolean **default:** true

Whether or not to include months in the input. This will result in an additional input to capture months.

#### `with_seconds`

**type:** Boolean **default:** false

Whether or not to include seconds in the input. This will result in an additional input to capture seconds.

#### `with_weeks`

**type:** Boolean **default:** false

Whether or not to include weeks in the input. This will result in an additional input to capture weeks.

This can not be used when `with_days` is enabled.

#### `with_years`

**type:** Boolean **default:** true

Whether or not to include years in the input. This will result in an additional input to capture years.

#### `years`

**type:** array **default:** 0 to 100

List of years available to the years field type. This option is only relevant when the `widget` option is set to `choice`:

Listing 32-11 `'years' => range(1, 100)`

## Inherited Options

These options inherit from the `form` type:

#### `data`

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 32-12 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the **inherit\_data** option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the **invalid\_message** option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 32-13 1 $builder->add('some_field', SomeFormType::class, array(
2     // ...
3     'invalid_message' => 'You entered an invalid value, it should include %num% letters',
```

```
4     'invalid_message_parameters' => array('%num%' => 6),
5  );
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the **mapped** option to **false**.

## Field Variables

Variable	Type	Usage
widget	mixed	The value of the widget option.
with_days	Boolean	The value of the with_days option.
with_invert	Boolean	The value of the with_invert option.
with_hours	Boolean	The value of the with_hours option.
with_minutes	Boolean	The value of the with_minutes option.
with_months	Boolean	The value of the with_months option.
with_seconds	Boolean	The value of the with_seconds option.
with_weeks	Boolean	The value of the with_weeks option.
with_years	Boolean	The value of the with_years option.

## Chapter 33

# DateTimeType Field

This field type allows the user to modify data that represents a specific date and time (e.g. **1984-06-05 12:15:30**).

Can be rendered as a text input or select tags. The underlying format of the data can be a **DateTime** object, a string, a timestamp or an array.

Underlying Data Type	can be <code>DateTime</code> , string, timestamp, or array (see the <code>input</code> option)
Rendered as	single text box or three select fields
Options	<ul style="list-style-type: none"><li>• <code>choice_translation_domain</code></li><li>• <code>date_format</code></li><li>• <code>date_widget</code></li><li>• <code>days</code></li><li>• <code>placeholder</code></li><li>• <code>format</code></li><li>• <code>hours</code></li><li>• <code>html5</code></li><li>• <code>input</code></li><li>• <code>minutes</code></li><li>• <code>model_timezone</code></li><li>• <code>months</code></li><li>• <code>seconds</code></li><li>• <code>time_widget</code></li><li>• <code>view_timezone</code></li><li>• <code>widget</code></li><li>• <code>with_minutes</code></li><li>• <code>with_seconds</code></li><li>• <code>years</code></li></ul>
Overridden options	<ul style="list-style-type: none"><li>• <code>by_reference</code></li></ul>

	<ul style="list-style-type: none"> <li>• compound</li> <li>• data_class</li> <li>• error_bubbling</li> </ul>
Inherited options	<ul style="list-style-type: none"> <li>• data</li> <li>• disabled</li> <li>• inherit_data</li> <li>• invalid_message</li> <li>• invalid_message_parameters</li> <li>• mapped</li> </ul>
Parent type	<i>FormType</i>
Class	<i>DateTimeType</i> <sup>1</sup>

## Field Options

### choice\_translation\_domain

**type:** string, boolean or null

This option determines if the choice values should be translated and in which translation domain.

The values of the `choice_translation_domain` option can be **true** (reuse the current translation domain), **false** (disable translation), **null** (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

### date\_format

**type:** integer or string **default:** IntlDateFormatter::MEDIUM

Defines the **format** option that will be passed down to the date field. See the `DateType`'s `format` option for more details.

### date\_widget

**type:** string **default:** choice

The basic way in which this field should be rendered. Can be one of the following:

- `choice`: renders three select inputs. The order of the selects is defined in the `format` option.
- `text`: renders a three field input of type text (month, day, year).
- `single_text`: renders a single input of type date. User's input is validated based on the `format` option.

### days

**type:** array **default:** 1 to 31

List of days available to the day field type. This option is only relevant when the `widget` option is set to `choice`:

Listing 33-1 `'days' => range(1,31)`

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/DateTimeType.html>

## placeholder

**type:** string | array

If your widget option is set to **choice**, then this field will be represented as a series of **select** boxes. When the placeholder value is a string, it will be used as the **blank value** of all select boxes:

```
Listing 33-2 1 use Symfony\Component\Form\Extension\Core\Type\DateTimeType;
2
3 $builder->add('startDateTime', DateTimeType::class, array(
4     'placeholder' => 'Select a value',
5 ));
```

Alternatively, you can use an array that configures different placeholder values for the year, month, day, hour, minute and second fields:

```
Listing 33-3 1 use Symfony\Component\Form\Extension\Core\Type\DateTimeType;
2
3 $builder->add('startDateTime', DateTimeType::class, array(
4     'placeholder' => array(
5         'year' => 'Year', 'month' => 'Month', 'day' => 'Day',
6         'hour' => 'Hour', 'minute' => 'Minute', 'second' => 'Second',
7     )
8 ));
```

## format

**type:** string **default:** `Symfony\Component\Form\Extension\Core\Type\DateTimeType::HTML5_FORMAT`

If the **widget** option is set to **single\_text**, this option specifies the format of the input, i.e. how Symfony will interpret the given input as a datetime string. It defaults to the *RFC 3339*<sup>2</sup> format which is used by the HTML5 **datetime** field. Keeping the default value will cause the field to be rendered as an **input** field with **type="datetime"**. For more information on valid formats, see *Date/Time Format Syntax*<sup>3</sup>.

## hours

**type:** array **default:** 0 to 23

List of hours available to the hours field type. This option is only relevant when the **widget** option is set to **choice**.

## html5

**type:** boolean **default:** true

If this is set to **true** (the default), it'll use the HTML5 type (date, time or datetime) to render the field. When set to **false**, it'll use the text type.

This is useful when you want to use a custom JavaScript datapicker, which often requires a text type instead of an HTML5 type.

## input

**type:** string **default:** datetime

---

2. <https://tools.ietf.org/html/rfc3339>

3. <http://userguide.icu-project.org/formatparse/datetime#TOC-Date-Time-Format-Syntax>

The format of the *input* data - i.e. the format that the date is stored on your underlying object. Valid values are:

- string (e.g. 2011-06-05 12:15:00)
- `datetime` (a `DateTime` object)
- array (e.g. `array(2011, 06, 05, 12, 15, 0)`)
- `timestamp` (e.g. 1307276100)

The value that comes back from the form will also be normalized back into this format.

If `timestamp` is used, `DateTime` is limited to dates between Fri, 13 Dec 1901 20:45:54 GMT and Tue, 19 Jan 2038 03:14:07 GMT on 32bit systems. This is due to a *limitation in PHP itself*<sup>4</sup>.

## minutes

**type:** array **default:** 0 to 59

List of minutes available to the minutes field type. This option is only relevant when the `widget` option is set to `choice`.

## model\_timezone

**type:** string **default:** system default timezone

Timezone that the input data is stored in. This must be one of the *PHP supported timezones*<sup>5</sup>.

## months

**type:** array **default:** 1 to 12

List of months available to the month field type. This option is only relevant when the `widget` option is set to `choice`.

## seconds

**type:** array **default:** 0 to 59

List of seconds available to the seconds field type. This option is only relevant when the `widget` option is set to `choice`.

## time\_widget

**type:** string **default:** choice

Defines the `widget` option for the *TimeType*.

## view\_timezone

**type:** string **default:** system default timezone

Timezone for how the data should be shown to the user (and therefore also the data that the user submits). This must be one of the *PHP supported timezones*<sup>6</sup>.

---

4. <https://php.net/manual/en/function.date.php#refsect1-function.date-changelog>

5. <https://php.net/manual/en/timezones.php>

6. <https://php.net/manual/en/timezones.php>

## widget

**type:** string **default:** null

Defines the **widget** option for both the *DateType* and *TimeType*. This can be overridden with the `date_widget` and `time_widget` options.

## with\_minutes

**type:** boolean **default:** true

Whether or not to include minutes in the input. This will result in an additional input to capture minutes.

## with\_seconds

**type:** boolean **default:** false

Whether or not to include seconds in the input. This will result in an additional input to capture seconds.

## years

**type:** array **default:** five years before to five years after the current year

List of years available to the year field type. This option is only relevant when the **widget** option is set to **choice**.

## Overridden Options

### by\_reference

**default:** false

The `DateTime` classes are treated as immutable objects.

### compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

### data\_class

**type:** string **default:** null

The internal normalized representation of this type is an array, not a `\DateTime` object. Therefore, the `data_class` option is initialized to **null** to avoid the `FormType` object from initializing it to `\DateTime`.

### error\_bubbling

**default:** false

# Inherited Options

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 33-4 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;  
2 // ...  
3  
4 $builder->add('token', HiddenType::class, array(  
5     'data' => 'abcdef',  
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the **inherit\_data** option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 33-5 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## Field Variables

Variable	Type	Usage
widget	mixed	The value of the widget option.
type	string	Only present when widget is <code>single_text</code> and HTML5 is activated, contains the input type to use ( <code>datetime</code> , <code>date</code> or <code>time</code> ).

## Chapter 34

# TimeType Field

A field to capture time input.

This can be rendered as a text field, a series of text fields (e.g. hour, minute, second) or a series of select fields. The underlying data can be stored as a `DateTime` object, a string, a timestamp or an array.

Underlying Data Type	can be <code>DateTime</code> , string, timestamp, or array (see the <code>input</code> option)
Rendered as	can be various tags (see below)
Options	<ul style="list-style-type: none"><li>• <code>choice_translation_domain</code></li><li>• <code>placeholder</code></li><li>• <code>hours</code></li><li>• <code>html5</code></li><li>• <code>input</code></li><li>• <code>minutes</code></li><li>• <code>model_timezone</code></li><li>• <code>seconds</code></li><li>• <code>view_timezone</code></li><li>• <code>widget</code></li><li>• <code>with_minutes</code></li><li>• <code>with_seconds</code></li></ul>
Overridden options	<ul style="list-style-type: none"><li>• <code>by_reference</code></li><li>• <code>compound</code></li><li>• <code>data_class</code></li><li>• <code>error_bubbling</code></li></ul>
Inherited Options	<ul style="list-style-type: none"><li>• <code>data</code></li><li>• <code>disabled</code></li><li>• <code>error_mapping</code></li><li>• <code>inherit_data</code></li></ul>

	<ul style="list-style-type: none"> <li>• <code>invalid_message</code></li> <li>• <code>invalid_message_parameters</code></li> <li>• <code>mapped</code></li> </ul>
Parent type	<code>FormType</code>
Class	<code>TimeType<sup>1</sup></code>

## Basic Usage

This field type is highly configurable, but easy to use. The most important options are `input` and `widget`.

Suppose that you have a `startTime` field whose underlying time data is a `DateTime` object. The following configures the `TimeType` for that field as two different choice fields:

Listing 34-1

```

1 use Symfony\Component\Form\Extension\Core\Type\TimeType;
2 // ...
3
4 $builder->add('startTime', TimeType::class, array(
5     'input' => 'datetime',
6     'widget' => 'choice',
7 ));

```

The `input` option *must* be changed to match the type of the underlying date data. For example, if the `startTime` field's data were a unix timestamp, you'd need to set `input` to `timestamp`:

Listing 34-2

```

1 use Symfony\Component\Form\Extension\Core\Type\TimeType;
2 // ...
3
4 $builder->add('startTime', TimeType::class, array(
5     'input' => 'timestamp',
6     'widget' => 'choice',
7 ));

```

The field also supports an `array` and `string` as valid `input` option values.

## Field Options

### `choice_translation_domain`

**type:** `string`, `boolean` or `null`

This option determines if the choice values should be translated and in which translation domain.

The values of the `choice_translation_domain` option can be `true` (reuse the current translation domain), `false` (disable translation), `null` (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

### `placeholder`

**type:** `string` | `array`

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/TimeType.html>

If your widget option is set to **choice**, then this field will be represented as a series of **select** boxes. When the placeholder value is a string, it will be used as the **blank value** of all select boxes:

```
Listing 34-3 $builder->add('startTime', 'time', array(
    'placeholder' => 'Select a value',
));
```

Alternatively, you can use an array that configures different placeholder values for the hour, minute and second fields:

```
Listing 34-4 1 $builder->add('startTime', 'time', array(
2     'placeholder' => array(
3         'hour' => 'Hour', 'minute' => 'Minute', 'second' => 'Second',
4     )
5 ));
```

## hours

**type:** array **default:** 0 to 23

List of hours available to the hours field type. This option is only relevant when the **widget** option is set to **choice**.

## html5

**type:** boolean **default:** true

If this is set to **true** (the default), it'll use the HTML5 type (date, time or datetime) to render the field. When set to **false**, it'll use the text type.

This is useful when you want to use a custom JavaScript datapicker, which often requires a text type instead of an HTML5 type.

## input

**type:** string **default:** datetime

The format of the *input* data - i.e. the format that the date is stored on your underlying object. Valid values are:

- string (e.g. 12:17:26)
- datetime (a DateTime object)
- array (e.g. array('hour' => 12, 'minute' => 17, 'second' => 26))
- timestamp (e.g. 1307232000)

The value that comes back from the form will also be normalized back into this format.

## minutes

**type:** array **default:** 0 to 59

List of minutes available to the minutes field type. This option is only relevant when the **widget** option is set to **choice**.

## model\_timezone

**type:** string **default:** system default timezone

Timezone that the input data is stored in. This must be one of the *PHP supported timezones*<sup>2</sup>.

## seconds

**type:** array **default:** 0 to 59

List of seconds available to the seconds field type. This option is only relevant when the **widget** option is set to **choice**.

## view\_timezone

**type:** string **default:** system default timezone

Timezone for how the data should be shown to the user (and therefore also the data that the user submits). This must be one of the *PHP supported timezones*<sup>3</sup>.

## widget

**type:** string **default:** choice

The basic way in which this field should be rendered. Can be one of the following:

- **choice:** renders one, two (default) or three select inputs (hour, minute, second), depending on the **with\_minutes** and **with\_seconds** options.
- **text:** renders one, two (default) or three text inputs (hour, minute, second), depending on the **with\_minutes** and **with\_seconds** options.
- **single\_text:** renders a single input of type **time**. User's input will be validated against the form **hh:mm** (or **hh:mm:ss** if using seconds).

Combining the widget type **single\_text** and the **with\_minutes** option set to **false** can cause unexpected behavior in the client as the input type **time** might not support selecting an hour only.

## with\_minutes

**type:** boolean **default:** true

Whether or not to include minutes in the input. This will result in an additional input to capture minutes.

## with\_seconds

**type:** boolean **default:** false

Whether or not to include seconds in the input. This will result in an additional input to capture seconds.

## Overridden Options

### by\_reference

**default:** false

The **DateTime** classes are treated as immutable objects.

---

2. <https://php.net/manual/en/timezones.php>

3. <https://php.net/manual/en/timezones.php>

## compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

## data\_class

**type:** string **default:** null

The internal normalized representation of this type is an array, not a `\DateTime` object. Therefore, the `data_class` option is initialized to `null` to avoid the `FormType` object from initializing it to `\DateTime`.

## error\_bubbling

**default:** false

# Inherited Options

These options inherit from the `FormType`:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 34-5 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The `data` option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 34-6 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 34-7 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the `inherit_data` option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 34-8 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## Form Variables

Variable	Type	Usage
widget	mixed	The value of the widget option.
with_minutes	boolean	The value of the with_minutes option.
with_seconds	boolean	The value of the with_seconds option.
type	string	Only present when widget is <code>single_text</code> and HTML5 is activated, contains the input type to use ( <code>datetime</code> , <code>date</code> or <code>time</code> ).

## Chapter 35

# BirthdateType Field

A *DateType* field that specializes in handling birthdate data.

Can be rendered as a single text box, three text boxes (month, day and year), or three select boxes.

This type is essentially the same as the *DateType* type, but with a more appropriate default for the years option. The years option defaults to 120 years ago to the current year.

Underlying Data Type	can be <code>DateTime</code> , <code>string</code> , <code>timestamp</code> , or <code>array</code> (see the input option)
Rendered as	can be three select boxes or 1 or 3 text boxes, based on the widget option
Overridden options	<ul style="list-style-type: none"><li>• <code>years</code></li></ul>
Inherited options	<p>from the <i>DateType</i>:</p> <ul style="list-style-type: none"><li>• <code>choice_translation_domain</code></li><li>• <code>days</code></li><li>• <code>placeholder</code></li><li>• <code>format</code></li><li>• <code>input</code></li><li>• <code>model_timezone</code></li><li>• <code>months</code></li><li>• <code>view_timezone</code></li><li>• <code>widget</code></li></ul> <p>from the <i>FormType</i>:</p> <ul style="list-style-type: none"><li>• <code>data</code></li><li>• <code>disabled</code></li><li>• <code>inherit_data</code></li><li>• <code>invalid_message</code></li><li>• <code>invalid_message_parameters</code></li><li>• <code>mapped</code></li></ul>

Parent type	<i>DateType</i>
Class	<i>BirthdateType</i> <sup>1</sup>

## Overridden Options

### years

**type:** array **default:** 120 years ago to the current year

List of years available to the year field type. This option is only relevant when the **widget** option is set to **choice**.

## Inherited Options

These options inherit from the *DateType*:

### choice\_translation\_domain

**type:** string, boolean or null

This option determines if the choice values should be translated and in which translation domain.

The values of the **choice\_translation\_domain** option can be **true** (reuse the current translation domain), **false** (disable translation), **null** (uses the parent translation domain or the default domain) or a string which represents the exact translation domain to use.

### days

**type:** array **default:** 1 to 31

List of days available to the day field type. This option is only relevant when the **widget** option is set to **choice**:

*Listing 35-1* `'days' => range(1,31)`

### placeholder

**type:** string | array

If your widget option is set to **choice**, then this field will be represented as a series of **select** boxes. When the placeholder value is a string, it will be used as the **blank value** of all select boxes:

*Listing 35-2*

```
$builder->add('birthdate', BirthdayType::class, array(
    'placeholder' => 'Select a value',
));
```

Alternatively, you can use an array that configures different placeholder values for the year, month and day fields:

*Listing 35-3*

```
1 $builder->add('birthdate', BirthdayType::class, array(
2     'placeholder' => array(
3         'year' => 'Year', 'month' => 'Month', 'day' => 'Day',
```

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/BirthdayType.html>

```
4     )
5   });
```

## format

**type:** integer or string **default:** `IntlDateFormatter::MEDIUM`<sup>2</sup> (or `yyyy-MM-dd` if widget is `single_text`)

Option passed to the `IntlDateFormatter` class, used to transform user input into the proper format. This is critical when the widget option is set to `single_text` and will define how the user will input the data. By default, the format is determined based on the current user locale: meaning that *the expected format will be different for different users*. You can override it by passing the format as a string.

For more information on valid formats, see *Date/Time Format Syntax*<sup>3</sup>:

```
Listing 35-4 1 use Symfony\Component\Form\Extension\Core\Type\DateType;
2 // ...
3
4 $builder->add('date_created', DateType::class, array(
5     'widget' => 'single_text',
6     // this is actually the default format for single_text
7     'format' => 'yyyy-MM-dd',
8 ));
```

If you want your field to be rendered as an HTML5 "date" field, you have to use a `single_text` widget with the `yyyy-MM-dd` format (the RFC 3339<sup>4</sup> format) which is the default value if you use the `single_text` widget.

## input

**type:** string **default:** `datetime`

The format of the *input* data - i.e. the format that the date is stored on your underlying object. Valid values are:

- string (e.g. 2011-06-05)
- `datetime` (a `DateTime` object)
- array (e.g. `array('year' => 2011, 'month' => 06, 'day' => 05)`)
- `timestamp` (e.g. 1307232000)

The value that comes back from the form will also be normalized back into this format.

If `timestamp` is used, `DateType` is limited to dates between Fri, 13 Dec 1901 20:45:54 GMT and Tue, 19 Jan 2038 03:14:07 GMT on 32bit systems. This is due to a *limitation in PHP itself*<sup>5</sup>.

## model\_timezone

**type:** string **default:** system default timezone

Timezone that the input data is stored in. This must be one of the *PHP supported timezones*<sup>6</sup>.

---

2. <https://php.net/manual/en/class.intlformatter.php#intl.intlformatter.constants>

3. <http://userguide.icu-project.org/formatparse/datetime#TOC-Date-Time-Format-Syntax>

4. <https://tools.ietf.org/html/rfc3339>

5. <https://php.net/manual/en/function.date.php#refsect1-function.date-changelog>

## months

**type:** array **default:** 1 to 12

List of months available to the month field type. This option is only relevant when the **widget** option is set to **choice**.

## view\_timezone

**type:** string **default:** system default timezone

Timezone for how the data should be shown to the user (and therefore also the data that the user submits). This must be one of the *PHP supported timezones*<sup>7</sup>.

## widget

**type:** string **default:** choice

The basic way in which this field should be rendered. Can be one of the following:

- **choice:** renders three select inputs. The order of the selects is defined in the format option.
- **text:** renders a three field input of type **text** (month, day, year).
- **single\_text:** renders a single input of type **date**. User's input is validated based on the format option.

These options inherit from the *FormType*:

## data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 35-5

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## inherit\_data

**type:** boolean **default:** false

---

6. <https://php.net/manual/en/timezones.php>

7. <https://php.net/manual/en/timezones.php>

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the `inherit_data` option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 35-6 1 $builder->add('some_field', SomeFormType::class, array(  
2 // ...  
3 'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4 'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## Chapter 36

# CheckboxType Field

Creates a single input checkbox. This should always be used for a field that has a boolean value: if the box is checked, the field will be set to true, if the box is unchecked, the value will be set to false.

Rendered as	input checkbox field
Options	<ul style="list-style-type: none"><li>• value</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li><li>• empty_data</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>CheckboxType</i> <sup>1</sup>

## Example Usage

Listing 36-1

```
1 use Symfony\Component\Form\Extension\Core\Type\CheckboxType;
2 // ...
```

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/CheckboxType.html>

```

3
4 $builder->add('public', CheckboxType::class, array(
5     'label' => 'Show this entry publicly?',
6     'required' => false,
7 ));

```

## Field Options

value

**type:** mixed **default:** 1

The value that's actually used as the value for the checkbox or radio button. This does not affect the value that's set on your object.

To make a checkbox or radio button checked by default, use the `data` option.

## Overridden Options

compound

**type:** boolean **default:** false

This option specifies if a form is compound. As it's not the case for checkbox, by default the value is overridden with the `false` value.

empty\_data

**type:** string **default:** mixed

This option determines what value the field will return when the `placeholder` choice is selected. In the checkbox and the radio type, the value of `empty_data` is overridden by the value returned by the data transformer (see *How to Use Data Transformers*).

## Inherited Options

These options inherit from the *FormType*:

data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the `data` option:

Listing 36-2

```

1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3

```

```

4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));

```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```

Listing 36-3 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }

```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 36-4 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.T' => 'city',
4     ),
5 ));
```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 36-5 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 36-6 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 36-7 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Form Variables

Variable	Type	Usage
<code>checked</code>	boolean	Whether or not the current input is checked.

---

2. <http://diveintohtml5.info/forms.html>

## Chapter 37

# FileType Field

The **FileType** represents a file input in your form.

Rendered as	input file field
Options	<ul style="list-style-type: none"><li>• multiple</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• compound</li><li>• data_class</li><li>• empty_data</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• disabled</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>FileType</i> <sup>1</sup>

## Basic Usage

Say you have this form definition:

Listing 37-1

```
use Symfony\Component\Form\Extension\Core\Type\FileType;
// ...
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/FileType.html>

```
$builder->add('attachment', FileType::class);
```

When the form is submitted, the `attachment` field will be an instance of *UploadedFile*<sup>2</sup>. It can be used to move the `attachment` file to a permanent location:

```
Listing 37-2 1 use Symfony\Component\HttpFoundation\File\UploadedFile;
2
3 public function upload()
4 {
5     // ...
6
7     if ($form->isSubmitted() && $form->isValid()) {
8         $someNewFilename = ...
9
10        $file = $form['attachment']->getData();
11        $file->move($directory, $someNewFilename);
12
13        // ...
14    }
15
16    // ...
17 }
```

The `move()` method takes a directory and a file name as its arguments. You might calculate the filename in one of the following ways:

```
Listing 37-3 1 // use the original file name
2 $file->move($directory, $file->getClientOriginalName());
3
4 // compute a random name and try to guess the extension (more secure)
5 $extension = $file->guessExtension();
6 if (!$extension) {
7     // extension cannot be guessed
8     $extension = 'bin';
9 }
10 $file->move($directory, rand(1, 99999).'.'.$extension);
```

Using the original name via `getClientOriginalName()` is not safe as it could have been manipulated by the end-user. Moreover, it can contain characters that are not allowed in file names. You should sanitize the name before using it directly.

Read *How to Upload Files* for an example of how to manage a file upload associated with a Doctrine entity.

## Field Options

multiple

**type:** Boolean **default:** false

When set to true, the user will be able to upload multiple files at the same time.

## Overridden Options

compound

**type:** boolean **default:** false

---

2. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/File/UploadedFile.html>

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

### `data_class`

**type:** `string` **default:** `File3`

This option sets the appropriate file-related data mapper to be used by the type.

### `empty_data`

**type:** `mixed` **default:** `null`

This option determines what value the field will return when the submitted value is empty.

## Inherited Options

These options inherit from the *FormType*:

### `disabled`

**type:** `boolean` **default:** `false`

If you don't want a user to modify the value of a field, you can set the `disabled` option to `true`. Any submitted value will be ignored.

### `error_bubbling`

**type:** `boolean` **default:** `false` unless the form is `compound`

If `true`, any errors for this field will be passed to the parent field or form. For example, if set to `true` on a normal field, any errors for that field will be attached to the main form, not to the specific field.

### `error_mapping`

**type:** `array` **default:** `array()`

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 37-4 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

---

3. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/File/File.html>

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 37-5 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 37-6 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 37-7 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 37-8 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
```

```
7     'label_format' => 'form.address.%name%',
8   ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type: boolean default: true**

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type: boolean default: true**

If true, an *HTML5 required attribute*<sup>4</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The required option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Form Variables

Variable	Type	Usage
<code>type</code>	string	The type variable is set to <code>file</code> , in order to render as a file input field.

4. <http://diveintohtml5.info/forms.html>

## Chapter 38

# RadioType Field

Creates a single radio button. If the radio button is selected, the field will be set to the specified value. Radio buttons cannot be unchecked - the value only changes when another radio button with the same name gets checked.

The **RadioType** isn't usually used directly. More commonly it's used internally by other types such as *ChoiceType*. If you want to have a boolean field, use *CheckboxType*.

Rendered as	input radio field
Inherited options	from the <i>CheckboxType</i> : <ul style="list-style-type: none"><li>• value</li></ul> from the <i>FormType</i> : <ul style="list-style-type: none"><li>• data</li><li>• disabled</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>CheckboxType</i>
Class	<i>RadioType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/RadioType.html>

## Inherited Options

These options inherit from the *CheckboxType*:

### value

**type:** mixed **default:** 1

The value that's actually used as the value for the checkbox or radio button. This does not affect the value that's set on your object.

To make a checkbox or radio button checked by default, use the data option.

These options inherit from the *FormType*:

### data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

Listing 38-1

```
1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

### empty\_data

**type:** string **default:** mixed

This option determines what value the field will return when the **placeholder** choice is selected. In the checkbox and the radio type, the value of **empty\_data** is overridden by the value returned by the data transformer (see *How to Use Data Transformers*).

### error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 38-2 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 38-3 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 38-4 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 38-5 1 {{ form_label(form.name, 'Your name', {
2             'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}}
3         )}}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 38-6 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Form Variables

Variable	Type	Usage
<code>checked</code>	<code>boolean</code>	Whether or not the current input is checked.

---

## Chapter 39

# CollectionType Field

This field type is used to render a "collection" of some field or form. In the easiest sense, it could be an array of **TextType** fields that populate an array **emails** values. In more complex examples, you can embed entire forms, which is useful when creating forms that expose one-to-many relationships (e.g. a product from where you can manage many related product photos).

Rendered as	depends on the entry_type option
Options	<ul style="list-style-type: none"><li>• allow_add</li><li>• allow_delete</li><li>• delete_empty</li><li>• entry_options</li><li>• entry_type</li><li>• prototype</li><li>• prototype_data</li><li>• prototype_name</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• by_reference</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• required</li></ul>
Parent type	<i>FormType</i>
Class	<i>CollectionType</i> <sup>1</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/CollectionType.html>

If you are working with a collection of Doctrine entities, pay special attention to the `allow_add`, `allow_delete` and `by_reference` options. You can also see a complete example in the *How to Embed a Collection of Forms* article.

## Basic Usage

This type is used when you want to manage a collection of similar items in a form. For example, suppose you have an `emails` field that corresponds to an array of email addresses. In the form, you want to expose each email address as its own input text box:

```
Listing 39-1 1 use Symfony\Component\Form\Extension\Core\Type\CollectionType;
2 use Symfony\Component\Form\Extension\Core\Type\EmailType;
3 // ...
4
5 $builder->add('emails', CollectionType::class, array(
6     // each entry in the array will be an "email" field
7     'entry_type' => EmailType::class,
8     // these options are passed to each "email" type
9     'entry_options' => array(
10        'attr' => array('class' => 'email-box'),
11    ),
12 ));
```

The simplest way to render this is all at once:

```
Listing 39-2 1 {{ form_row(form.emails) }}
```

A much more flexible method would look like this:

```
Listing 39-3 1 {{ form_label(form.emails) }}
2 {{ form_errors(form.emails) }}
3
4 <ul>
5 {% for emailField in form.emails %}
6     <li>
7         {{ form_errors(emailField) }}
8         {{ form_widget(emailField) }}
9     </li>
10 {% endfor %}
11 </ul>
```

In both cases, no input fields would render unless your `emails` data array already contained some emails.

In this simple example, it's still impossible to add new addresses or remove existing addresses. Adding new addresses is possible by using the `allow_add` option (and optionally the `prototype` option) (see example below). Removing emails from the `emails` array is possible with the `allow_delete` option.

## Adding and Removing Items

If `allow_add` is set to `true`, then if any unrecognized items are submitted, they'll be added seamlessly to the array of items. This is great in theory, but takes a little bit more effort in practice to get the client-side JavaScript correct.

Following along with the previous example, suppose you start with two emails in the `emails` data array. In that case, two input fields will be rendered that will look something like this (depending on the name of your form):

Listing 39-4

```

1 <input type="email" id="form_emails_0" name="form[emails][0]" value="foo@foo.com" />
2 <input type="email" id="form_emails_1" name="form[emails][1]" value="bar@bar.com" />

```

To allow your user to add another email, just set `allow_add` to `true` and - via JavaScript - render another field with the name `form[emails][2]` (and so on for more and more fields).

To help make this easier, setting the `prototype` option to `true` allows you to render a "template" field, which you can then use in your JavaScript to help you dynamically create these new fields. A rendered prototype field will look like this:

Listing 39-5

```

1 <input type="email"
2   id="form_emails__name__"
3   name="form[emails][__name__]"
4   value=""
5 />

```

By replacing `__name__` with some unique value (e.g. `2`), you can build and insert new HTML fields into your form.

Using jQuery, a simple example might look like this. If you're rendering your collection fields all at once (e.g. `form_row(form.emails)`), then things are even easier because the `data-prototype` attribute is rendered automatically for you (with a slight difference - see note below) and all you need is this JavaScript code:

Listing 39-6

```

1 // add-collection-widget.js
2 jQuery(document).ready(function () {
3   jQuery('.add-another-collection-widget').click(function (e) {
4     e.preventDefault();
5     var list = jQuery(jQuery(this).attr('data-list'));
6     // Try to find the counter of the list
7     var counter = list.data('widget-counter') | list.children().length;
8     // If the counter does not exist, use the length of the list
9     if (!counter) { counter = list.children().length; }
10
11    // grab the prototype template
12    var newWidget = list.attr('data-prototype');
13    // replace the "__name__" used in the id and name of the prototype
14    // with a number that's unique to your emails
15    // end name attribute looks like name="contact[emails][2]"
16    newWidget = newWidget.replace(/__name__/g, counter);
17    // Increase the counter
18    counter++;
19    // And store it, the length cannot be used if deleting widgets is allowed
20    list.data(' widget-counter', counter);
21
22    // create a new list element and add it to the list
23    var newElem = jQuery(list.attr('data-widget-tags')).html(newWidget);
24    newElem.appendTo(list);
25  });
26 });

```

And update the template as follows:

Listing 39-7

```

1 {{ form_start(form) }}
2   {# ... #}
3
4   {# store the prototype on the data-prototype attribute #}
5   <ul id="email-fields-list"
6     data-prototype="{{ form_widget(form.emails.vars.prototype)|e }}"
7     data-widget-tags="{{ '<li></li>' |e }}">
8     {% for emailField in form.emails %}
9       <li>
10        {{ form_errors(emailField) }}
11        {{ form_widget(emailField) }}
12      </li>

```

```

13     {% endfor %}
14 </ul>
15
16     <a href="#"
17         class="add-another-collection-widget"
18         data-list="#email-fields-list">Add another email</a>
19
20     {# ... #}
21 {{ form_end(form) }}
22
23 <script src="add-collection-widget.js"></script>

```

If you're rendering the entire collection at once, then the prototype is automatically available on the **data-prototype** attribute of the element (e.g. **div** or **table**) that surrounds your collection. The only difference is that the entire "form row" is rendered for you, meaning you wouldn't have to wrap it in any container element as it was done above.

## Field Options

### allow\_add

**type:** boolean **default:** false

If set to **true**, then if unrecognized items are submitted to the collection, they will be added as new items. The ending array will contain the existing items as well as the new item that was in the submitted data. See the above example for more details.

The prototype option can be used to help render a prototype item that can be used - with JavaScript - to create new form items dynamically on the client side. For more information, see the above example and [Allowing "new" Tags with the "Prototype"](#).

If you're embedding entire other forms to reflect a one-to-many database relationship, you may need to manually ensure that the foreign key of these new objects is set correctly. If you're using Doctrine, this won't happen automatically. See the above link for more details.

### allow\_delete

**type:** boolean **default:** false

If set to **true**, then if an existing item is not contained in the submitted data, it will be correctly absent from the final array of items. This means that you can implement a "delete" button via JavaScript which simply removes a form element from the DOM. When the user submits the form, its absence from the submitted data will mean that it's removed from the final array.

For more information, see [Allowing Tags to be Removed](#).

Be careful when using this option when you're embedding a collection of objects. In this case, if any embedded forms are removed, they *will* correctly be missing from the final array of objects. However, depending on your application logic, when one of those objects is removed, you may want to delete it or at least remove its foreign key reference to the main object. None of this is handled automatically. For more information, see [Allowing Tags to be Removed](#).

## delete\_empty

**type:** Boolean or callable **default:** false

If you want to explicitly remove entirely empty collection entries from your form you have to set this option to **true**. However, existing collection entries will only be deleted if you have the `allow_delete` option enabled. Otherwise the empty values will be kept.

The `delete_empty` option only removes items when the normalized value is **null**. If the nested `entry_type` is a compound form type, you must either set the **required** option to **false** or set the **empty\_data** option to **null**. Both of these options can be set inside `entry_options`. Read about the form's `empty_data` option to learn why this is necessary.

A value is deleted from the collection only if the normalized value is **null**. However, you can also set the option value to a callable, which will be executed for each value in the submitted collection. If the callable returns **true**, the value is removed from the collection. For example:

```
Listing 39-8 1 use Symfony\Component\Form\Extension\Core\Type\CollectionType;
2 // ...
3
4 $builder->add('users', CollectionType::class, array(
5     // ...
6     'delete_empty' => function (User $user = null) {
7         return null === $user || empty($user->getFirstName());
8     },
9 ));
```

Using a callable is particularly useful in case of compound form types, which may define complex conditions for considering them empty.

## entry\_options

**type:** array **default:** array()

This is the array that's passed to the form type specified in the `entry_type` option. For example, if you used the *ChoiceType* as your `entry_type` option (e.g. for a collection of drop-down menus), then you'd need to at least pass the **choices** option to the underlying type:

```
Listing 39-9 1 use Symfony\Component\Form\Extension\Core\Type\CollectionType;
2 use Symfony\Component\Form\Extension\Core\Type\ChoiceType;
3 // ...
4
5 $builder->add('favorite_cities', CollectionType::class, array(
6     'entry_type' => ChoiceType::class,
7     'entry_options' => array(
8         'choices' => array(
9             'Nashville' => 'nashville',
10            'Paris' => 'paris',
11            'Berlin' => 'berlin',
12            'London' => 'london',
13        ),
14    ),
15 ));
```

## entry\_type

**type:** string **default:** `Symfony\Component\Form\Extension\Core\Type\TextType`

This is the field type for each item in this collection (e.g. `TextType`, `ChoiceType`, etc). For example, if you have an array of email addresses, you'd use the `EmailType`. If you want to embed a collection of some other form, pass the form type class as this option (e.g. `MyFormType::class`).

## prototype

**type:** `boolean` **default:** `true`

This option is useful when using the `allow_add` option. If `true` (and if `allow_add` is also `true`), a special "prototype" attribute will be available so that you can render a "template" example on your page of what a new element should look like. The `name` attribute given to this element is `__name__`. This allows you to add a "add another" button via JavaScript which reads the prototype, replaces `__name__` with some unique name or number and render it inside your form. When submitted, it will be added to your underlying array due to the `allow_add` option.

The prototype field can be rendered via the `prototype` variable in the collection field:

```
Listing 39-10 1 {{ form_row(form.emails.vars.prototype) }}
```

Note that all you really need is the "widget", but depending on how you're rendering your form, having the entire "form row" may be easier for you.

If you're rendering the entire collection field at once, then the prototype form row is automatically available on the `data-prototype` attribute of the element (e.g. `div` or `table`) that surrounds your collection.

For details on how to actually use this option, see the above example as well as [Allowing "new" Tags with the "Prototype"](#).

## prototype\_data

**type:** `mixed` **default:** `null`

Allows you to define specific data for the prototype. Each new row added will initially contain the data set by this option. By default, the data configured for all entries with the `entry_options` option will be used.

```
Listing 39-11 1 use Symfony\Component\Form\Extension\Core\Type\CollectionType;
2 use Symfony\Component\Form\Extension\Core\Type\TextType;
3 // ...
4
5 $builder->add('tags', CollectionType::class, array(
6     'entry_type' => TextType::class,
7     'allow_add' => true,
8     'prototype' => true,
9     'prototype_data' => 'New Tag Placeholder',
10 ));
```

## prototype\_name

**type:** `string` **default:** `__name__`

If you have several collections in your form, or worse, nested collections you may want to change the placeholder so that unrelated placeholders are not replaced with the same value.

## Inherited Options

These options inherit from the *FormType*. Not all options are listed here - only the most applicable to this type:

### by\_reference

**type:** boolean **default:** true

In most cases, if you have an **author** field, then you expect **setAuthor()** to be called on the underlying object. In some cases, however, **setAuthor()** may *not* be called. Setting **by\_reference** to **false** ensures that the setter is called in all cases.

To explain this further, here's a simple example:

```
Listing 39-12 1 use Symfony\Component\Form\Extension\Core\Type\TextType;
2 use Symfony\Component\Form\Extension\Core\Type\EmailType;
3 use Symfony\Component\Form\Extension\Core\Type\FormType;
4 // ...
5
6 $builder = $this->createFormBuilder($article);
7 $builder
8     ->add('title', TextType::class)
9     ->add(
10         $builder->create('author', FormType::class, array('by_reference' => ?))
11         ->add('name', TextType::class)
12         ->add('email', EmailType::class)
13     )
```

If **by\_reference** is true, the following takes place behind the scenes when you call **submit()** (or **handleRequest()**) on the form:

```
Listing 39-13 $article->setTitle('...');
$article->getAuthor()->setName('...');
$article->getAuthor()->setEmail('...');
```

Notice that **setAuthor()** is not called. The author is modified by reference.

If you set **by\_reference** to false, submitting looks like this:

```
Listing 39-14 1 $article->setTitle('...');
2 $author = clone $article->getAuthor();
3 $author->setName('...');
4 $author->setEmail('...');
5 $article->setAuthor($author);
```

So, all that **by\_reference=false** really does is force the framework to call the setter on the parent object.

Similarly, if you're using the *CollectionType* field where your underlying collection data is an object (like with Doctrine's *ArrayCollection*), then **by\_reference** must be set to **false** if you need the adder and remover (e.g. **addAuthor()** and **removeAuthor()**) to be called.

### empty\_data

**type:** mixed

The default value is **array()** (empty array).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 39-15 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** true

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named **matchingCityAndZipCode()** that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 39-16 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;

- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (.) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 39-17 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.*' => 'city',
4     ),
5 ));
```

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 39-18 1 {{ form_label(form.name, 'Your name') }}
```

## label\_attr

**type: array default:** `array()`

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 39-19 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default:** `null`

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 39-20 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>2</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## Field Variables

Variable	Type	Usage
<code>allow_add</code>	boolean	The value of the <code>allow_add</code> option.
<code>allow_delete</code>	boolean	The value of the <code>allow_delete</code> option.

---

## Chapter 40

# RepeatedType Field

This is a special field "group", that creates two identical fields whose values must match (or a validation error is thrown). The most common use is when you need the user to repeat their password or email to verify accuracy.

Rendered as	input text field by default, but see type option
Options	<ul style="list-style-type: none"><li>• first_name</li><li>• first_options</li><li>• options</li><li>• second_name</li><li>• second_options</li><li>• type</li></ul>
Overridden options	<ul style="list-style-type: none"><li>• error_bubbling</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• error_mapping</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• mapped</li></ul>
Parent type	<i>FormType</i>
Class	<i>RepeatedType</i> <sup>1</sup>

## Example Usage

Listing 40-1

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/RepeatedType.html>

```

1 use Symfony\Component\Form\Extension\Core\Type\RepeatedType;
2 use Symfony\Component\Form\Extension\Core\Type\PasswordType;
3 // ...
4
5 $builder->add('password', RepeatedType::class, array(
6     'type' => PasswordType::class,
7     'invalid_message' => 'The password fields must match.',
8     'options' => array('attr' => array('class' => 'password-field')),
9     'required' => true,
10    'first_options' => array('label' => 'Password'),
11    'second_options' => array('label' => 'Repeat Password'),
12 ));

```

Upon a successful form submit, the value entered into both of the "password" fields becomes the data of the **password** key. In other words, even though two fields are actually rendered, the end data from the form is just the single value (usually a string) that you need.

The most important option is **type**, which can be any field type and determines the actual type of the two underlying fields. The **options** option is passed to each of those individual fields, meaning - in this example - any option supported by the **PasswordType** can be passed in this array.

## Rendering

The repeated field type is actually two underlying fields, which you can render all at once, or individually. To render all at once, use something like:

Listing 40-2 

```
1 {{ form_row(form.password) }}
```

To render each field individually, use something like this:

Listing 40-3 

```

1 {# .first and .second may vary in your use - see the note below #}
2 {{ form_row(form.password.first) }}
3 {{ form_row(form.password.second) }}

```

The names **first** and **second** are the default names for the two sub-fields. However, these names can be controlled via the `first_name` and `second_name` options. If you've set these options, then use those values instead of **first** and **second** when rendering.

## Validation

One of the key features of the **repeated** field is internal validation (you don't need to do anything to set this up) that forces the two fields to have a matching value. If the two fields don't match, an error will be shown to the user.

The `invalid_message` is used to customize the error that will be displayed when the two fields do not match each other.

## Field Options

### first\_name

**type:** string **default:** first

This is the actual field name to be used for the first field. This is mostly meaningless, however, as the actual data entered into both of the fields will be available under the key assigned to the **RepeatedType**

field itself (e.g. `password`). However, if you don't specify a label, this field name is used to "guess" the label for you.

### first\_options

**type:** array **default:** array()

Additional options (will be merged into options below) that should be passed *only* to the first field. This is especially useful for customizing the label:

```
Listing 40-4 1 use Symfony\Component\Form\Extension\Core\Type\RepeatedType;
2 // ...
3
4 $builder->add('password', RepeatedType::class, array(
5     'first_options' => array('label' => 'Password'),
6     'second_options' => array('label' => 'Repeat Password'),
7 ));
```

### options

**type:** array **default:** array()

This options array will be passed to each of the two underlying fields. In other words, these are the options that customize the individual field types. For example, if the **type** option is set to `password`, this array might contain the options `always_empty` or `required` - both options that are supported by the `PasswordType` field.

### second\_name

**type:** string **default:** second

The same as `first_name`, but for the second field.

### second\_options

**type:** array **default:** array()

Additional options (will be merged into options above) that should be passed *only* to the second field. This is especially useful for customizing the label (see `first_options`).

### type

**type:** string **default:** `Symfony\Component\Form\Extension\Core\Type\TextType`

The two underlying fields will be of this field type. For example, passing `PasswordType::class` will render two password fields.

## Overridden Options

### error\_bubbling

**default:** false

# Inherited Options

These options inherit from the *FormType*:

## data

**type:** **mixed** **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 40-5 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## error\_mapping

**type:** **array** **default:** **array()**

This option allows you to modify the target of a validation error.

Imagine you have a custom method named **matchingCityAndZipCode()** that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 40-6 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an `array` or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the **city** field, use:

```
Listing 40-7 1 $resolver->setDefaults(array(  
2     'error_mapping' => array(  
3         '.T' => 'city',  
4     ),  
5 ));
```

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 40-8 1 $builder->add('some_field', SomeFormType::class, array(  
2     // ...  
3     'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4     'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## Chapter 41

# HiddenType Field

The hidden type represents a hidden input field.

Rendered as	input hidden field
Overridden options	<ul style="list-style-type: none"><li>• compound</li><li>• error_bubbling</li><li>• required</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• data</li><li>• error_mapping</li><li>• mapped</li><li>• property_path</li></ul>
Parent type	<i>FormType</i>
Class	<i>HiddenType</i> <sup>1</sup>

## Overridden Options

### compound

**type:** boolean **default:** false

This option specifies whether the type contains child types or not. This option is managed internally for built-in types, so there is no need to configure it explicitly.

### error\_bubbling

**default:** true

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/HiddenType.html>

Pass errors to the root form, otherwise they will not be visible.

## required

**default:** false

Hidden fields cannot have a required attribute.

## Inherited Options

These options inherit from the *FormType*:

### data

**type:** mixed **default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 41-1 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
2 // ...
3
4 $builder->add('token', HiddenType::class, array(
5     'data' => 'abcdef',
6 ));
```

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

### error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 41-2 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;

- If the violation is generated on an entry of an `array` or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 41-3 1 $resolver->setDefaults(array(  
2     'error_mapping' => array(  
3         '.' => 'city',  
4     ),  
5 ));
```

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the `mapped` option to `false`.

## property\_path

**type:** `PropertyPathInterface|string|null` **default:** null

Fields display a property value of the form's domain object by default. When the form is submitted, the submitted value is written back into the object.

If you want to override the property that a field reads from and writes to, you can set the `property_path` option. Its default value (`null`) will use the field's name as the property.

## Chapter 42

# ButtonType Field

A simple, non-responsive button.

Rendered as	button tag
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• disabled</li><li>• label</li><li>• translation_domain</li></ul>
Parent type	none
Class	<i>ButtonType</i> <sup>1</sup>

## Inherited Options

The following options are defined in the *ButtonType*<sup>2</sup> class. The **ButtonType** class is the parent class for both the **button** type and the *FormType*, but it is not part of the form type tree (i.e. it cannot be used as a form type on its own).

**attr**

**type:** array **default:** array()

If you want to add extra attributes to the HTML representation of the button, you can use **attr** option. It's an associative array with HTML attribute as a key. This can be useful when you need to set a custom class for the button:

```
Listing 42-1 1 use Symfony\Component\Form\Extension\Core\Type\ButtonType;  
2 // ...  
3
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/ButtonType.html>

2. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/BaseType.html>

```
4 $builder->add('save', ButtonType::class, array(
5     'attr' => array('class' => 'save'),
6 ));
```

## disabled

**type:** boolean **default:** false

If you don't want a user to be able to click a button, you can set the disabled option to true. It will not be possible to submit the form with this button, not even when bypassing the browser and sending a request manually, for example with cURL.

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be displayed on the button. The label can also be directly set inside the template:

```
Listing 42-2 1 {{ form_widget(form.save, { 'label': 'Click me' }) }}
```

## translation\_domain

**type:** string **default:** messages

This is the translation domain that will be used for any labels or options that are rendered for this button.

## Chapter 43

# ResetType Field

A button that resets all fields to their original values.

Rendered as	input reset tag
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• disabled</li><li>• label</li><li>• label_attr</li><li>• translation_domain</li></ul>
Parent type	<i>ButtonType</i>
Class	<i>ResetType</i> <sup>1</sup>

## Inherited Options

**attr**

**type:** array **default:** array()

If you want to add extra attributes to the HTML representation of the button, you can use **attr** option. It's an associative array with HTML attribute as a key. This can be useful when you need to set a custom class for the button:

```
Listing 43-1 1 use Symfony\Component\Form\Extension\Core\Type\ResetType;
2 // ...
3
4 $builder->add('save', ResetType::class, array(
5     'attr' => array('class' => 'save'),
6 ));
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/ResetType.html>

## disabled

**type:** boolean **default:** false

If you don't want a user to be able to click a button, you can set the disabled option to true. It will not be possible to submit the form with this button, not even when bypassing the browser and sending a request manually, for example with cURL.

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be displayed on the button. The label can also be directly set inside the template:

```
Listing 43-2 1 {{ form_widget(form.save, { 'label': 'Click me' }) }}
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 43-3 1 {{ form_label(form.name, 'Your name', {  
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3 }) }}
```

## translation\_domain

**type:** string **default:** messages

This is the translation domain that will be used for any labels or options that are rendered for this button.

## Chapter 44

# SubmitType Field

A submit button.

Rendered as	button submit tag
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• disabled</li><li>• label</li><li>• label_attr</li><li>• label_format</li><li>• translation_domain</li><li>• validation_groups</li></ul>
Parent type	<i>ButtonType</i>
Class	<i>SubmitType</i> <sup>1</sup>

The Submit button has an additional method *isClicked()*<sup>2</sup> that lets you check whether this button was used to submit the form. This is especially useful when *a form has multiple submit buttons*:

```
Listing 44-1 if ($form->get('save')->isClicked()) {  
    // ...  
}
```

## Inherited Options

**attr**

**type:** array **default:** array()

---

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/SubmitType.html>  
2. [https://api.symfony.com/4.0/Symfony/Component/Form/ClickableInterface.html#method\\_isClicked](https://api.symfony.com/4.0/Symfony/Component/Form/ClickableInterface.html#method_isClicked)

If you want to add extra attributes to the HTML representation of the button, you can use **attr** option. It's an associative array with HTML attribute as a key. This can be useful when you need to set a custom class for the button:

```
Listing 44-2 1 use Symfony\Component\Form\Extension\Core\Type\SubmitType;
2 // ...
3
4 $builder->add('save', SubmitType::class, array(
5     'attr' => array('class' => 'save'),
6 ));
```

## disabled

**type: boolean default: false**

If you don't want a user to be able to click a button, you can set the disabled option to true. It will not be possible to submit the form with this button, not even when bypassing the browser and sending a request manually, for example with cURL.

## label

**type: string default:** The label is "guessed" from the field name

Sets the label that will be displayed on the button. The label can also be directly set inside the template:

```
Listing 44-3 1 {{ form_widget(form.save, { 'label': 'Click me' }) }}
```

## label\_attr

**type: array default: array()**

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 44-4 1 {{ form_label(form.name, 'Your name', {
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}
3 }) }}
```

## label\_format

**type: string default: null**

Configures the string used as the label of the field, in case the **label** option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. **profile\_address\_street**, **invoice\_address\_street**). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

```
Listing 44-5 1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
```

```

7     'label_format' => 'form.address.%name%',
8 );

```

This option is inherited by the child types. With the code above, the label of the `street` field of both forms will use the `form.address.street` keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The `label_format` option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## translation\_domain

**type:** string **default:** messages

This is the translation domain that will be used for any labels or options that are rendered for this button.

## validation\_groups

**type:** array **default:** null

When your form contains multiple submit buttons, you can change the validation group based on the button which was used to submit the form. Imagine a registration form wizard with buttons to go to the previous or the next step:

```

Listing 44-6 1 use Symfony\Component\Form\Extension\Core\Type\SubmitType;
2 // ...
3
4 $form = $this->createFormBuilder($user)
5     ->add('previousStep', SubmitType::class, array(
6         'validation_groups' => false,
7     ))
8     ->add('nextStep', SubmitType::class, array(
9         'validation_groups' => array('Registration'),
10    ))
11    ->getForm();

```

The special `false` ensures that no validation is performed when the previous step button is clicked. When the second button is clicked, all constraints from the "Registration" are validated.

*You can read more about this in [How to Choose Validation Groups Based on the Submitted Data](#).*

## Form Variables

Variable	Type	Usage
clicked	boolean	Whether the button is clicked or not.

## Chapter 45

# FormType Field

The **FormType** predefines a couple of options that are then available on all types for which **FormType** is the parent.

Options	<ul style="list-style-type: none"><li>• action</li><li>• allow_extra_fields</li><li>• by_reference</li><li>• compound</li><li>• constraints</li><li>• data</li><li>• data_class</li><li>• empty_data</li><li>• error_bubbling</li><li>• error_mapping</li><li>• extra_fields_message</li><li>• inherit_data</li><li>• invalid_message</li><li>• invalid_message_parameters</li><li>• label_attr</li><li>• label_format</li><li>• mapped</li><li>• method</li><li>• post_max_size_message</li><li>• property_path</li><li>• required</li><li>• trim</li></ul>
Inherited options	<ul style="list-style-type: none"><li>• attr</li><li>• auto_initialize</li><li>• block_name</li><li>• disabled</li><li>• label</li></ul>

	<ul style="list-style-type: none"> <li>translation_domain</li> </ul>
Parent	none
Class	<i>FormType</i> <sup>1</sup>

## Field Options

### action

**type:** string **default:** empty string

This option specifies where to send the form's data on submission (usually a URI). Its value is rendered as the **action** attribute of the **form** element. An empty value is considered a same-document reference, i.e. the form will be submitted to the same URI that rendered the form.

### allow\_extra\_fields

**type:** boolean **default:** false

Usually, if you submit extra fields that aren't configured in your form, you'll get a "This form should not contain extra fields." validation error.

You can silence this validation error by enabling the **allow\_extra\_fields** option on the form.

### by\_reference

**type:** boolean **default:** true

In most cases, if you have an **author** field, then you expect **setAuthor()** to be called on the underlying object. In some cases, however, **setAuthor()** may *not* be called. Setting **by\_reference** to **false** ensures that the setter is called in all cases.

To explain this further, here's a simple example:

```
Listing 45-1
1 use Symfony\Component\Form\Extension\Core\Type\TextType;
2 use Symfony\Component\Form\Extension\Core\Type\EmailType;
3 use Symfony\Component\Form\Extension\Core\Type\FormType;
4 // ...
5
6 $builder = $this->createFormBuilder($article);
7 $builder
8     ->add('title', TextType::class)
9     ->add(
10         $builder->create('author', FormType::class, array('by_reference' => ?))
11         ->add('name', TextType::class)
12         ->add('email', EmailType::class)
13     )
```

If **by\_reference** is true, the following takes place behind the scenes when you call **submit()** (or **handleRequest()**) on the form:

```
Listing 45-2
$article->setTitle('...');
$article->getAuthor()->setName('...');
$article->getAuthor()->setEmail('...');
```

Notice that **setAuthor()** is not called. The author is modified by reference.

1. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/FormType.html>

If you set `by_reference` to false, submitting looks like this:

```
Listing 45-3 1 $article->setTitle('...');
            2 $author = clone $article->getAuthor();
            3 $author->setName('...');
            4 $author->setEmail('...');
            5 $article->setAuthor($author);
```

So, all that `by_reference=false` really does is force the framework to call the setter on the parent object.

Similarly, if you're using the *CollectionType* field where your underlying collection data is an object (like with Doctrine's *ArrayCollection*), then `by_reference` must be set to `false` if you need the adder and remover (e.g. `addAuthor()` and `removeAuthor()`) to be called.

## compound

**type: boolean default: true**

If `true` this option creates the form as "compound", meaning that it can contain children and be a parent of other forms.

Most of the time you won't need to override this option. You might want to control for it when creating a custom form type with advanced rendering logic.

In a view a compound form is rendered as a `<div>` container or a `<form>` element (the whole form is obviously a compound form).

Non-compound forms are always leaves in a form tree, they cannot have children.

A non-compound form is rendered as one of the html form elements: `<input>` (*TextType*, *FileType*, *HiddenType*), `<textarea>` (*TextareaType*) or `<select>` (*ChoiceType*).

An interesting case is the *ChoiceType*. With `expanded=false` it is a non-compound form and is rendered as a `<select>` tag. With `expanded=true` the *ChoiceType* becomes a compound form and is rendered as a set of radios or checkboxes.

## constraints

**type: array or *Constraint*<sup>2</sup> default: null**

Allows you to attach one or more validation constraints to a specific field. For more information, see Adding Validation. This option is added in the *FormTypeValidatorExtension*<sup>3</sup> form extension.

## data

**type: mixed default:** Defaults to field of the underlying structure.

When you create a form, each field initially displays the value of the corresponding property of the form's domain data (e.g. if you bind an object to the form). If you want to override this initial value for the form or an individual field, you can set it in the data option:

```
Listing 45-4 1 use Symfony\Component\Form\Extension\Core\Type\HiddenType;
            2 // ...
            3
            4 $builder->add('token', HiddenType::class, array(
            5     'data' => 'abcdef',
            6 ));
```

---

2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraint.html>

3. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Validator/Type/FormTypeValidatorExtension.html>

The **data** option *always* overrides the value taken from the domain data (object) when rendering. This means the object value is also overridden when the form edits an already persisted object, causing it to lose its persisted value when the form is submitted.

## data\_class

### type: string

This option is used to set the appropriate data mapper to be used by the form, so you can use it for any form field type which requires an object:

```
Listing 45-5 1 use App\Entity\Media;
2 use App\Form\MediaType;
3 // ...
4
5 $builder->add('media', MediaType::class, array(
6     'data_class' => Media::class,
7 ));
```

## empty\_data

### type: mixed

The actual default value of this option depends on other field options:

- If `data_class` is set and `required` is true, then `new $data_class()`;
- If `data_class` is set and `required` is false, then `null`;
- If `data_class` is not set and `compound` is true, then `array()` (empty array);
- If `data_class` is not set and `compound` is false, then `''` (empty string).

This option determines what value the field will *return* when the submitted value is empty (or missing). It does not set an initial value if none is provided when the form is rendered in a view.

This means it helps you handling form submission with blank fields. For example, if you want the **name** field to be explicitly set to **John Doe** when no value is selected, you can do it like this:

```
Listing 45-6 $builder->add('name', null, array(
    'required' => false,
    'empty_data' => 'John Doe',
));
```

This will still render an empty text box, but upon submission the **John Doe** value will be set. Use the **data** or **placeholder** options to show this initial value in the rendered form.

If a form is compound, you can set **empty\_data** as an array, object or closure. See the *How to Configure empty Data for a Form Class* article for more details about these options.

If you want to set the **empty\_data** option for your entire form class, see the *How to Configure empty Data for a Form Class* article.

*Form data transformers* will still be applied to the **empty\_data** value. This means that an empty string will be cast to **null**. Use a custom data transformer if you explicitly want to return the empty string.

## error\_bubbling

**type:** boolean **default:** false unless the form is compound

If **true**, any errors for this field will be passed to the parent field or form. For example, if set to **true** on a normal field, any errors for that field will be attached to the main form, not to the specific field.

## error\_mapping

**type:** array **default:** array()

This option allows you to modify the target of a validation error.

Imagine you have a custom method named `matchingCityAndZipCode()` that validates whether the city and zip code match. Unfortunately, there is no "matchingCityAndZipCode" field in your form, so all that Symfony can do is display the error on top of the form.

With customized error mapping, you can do better: map the error to the city field so that it displays above it:

```
Listing 45-7 1 public function configureOptions(OptionsResolver $resolver)
2 {
3     $resolver->setDefaults(array(
4         'error_mapping' => array(
5             'matchingCityAndZipCode' => 'city',
6         ),
7     ));
8 }
```

Here are the rules for the left and the right side of the mapping:

- The left side contains property paths;
- If the violation is generated on a property or method of a class, its path is simply `propertyName`;
- If the violation is generated on an entry of an array or `ArrayAccess` object, the property path is `[indexName]`;
- You can construct nested property paths by concatenating them, separating properties by dots. For example: `addresses[work].matchingCityAndZipCode`;
- The right side contains simply the names of fields in the form.

By default, errors for any property that is not mapped will bubble up to the parent form. You can use the dot (`.`) on the left side to map errors of all unmapped properties to a particular field. For instance, to map all these errors to the `city` field, use:

```
Listing 45-8 1 $resolver->setDefaults(array(
2     'error_mapping' => array(
3         '.' => 'city',
4     ),
5 ));
```

## extra\_fields\_message

**type:** string **default:** This form should not contain extra fields.

This is the validation error message that's used if the submitted form data contains one or more fields that are not part of the form definition. The placeholder `{{ extra_fields }}` can be used to display a comma separated list of the submitted extra field names.

## inherit\_data

**type:** boolean **default:** false

This option determines if the form will inherit data from its parent form. This can be useful if you have a set of fields that are duplicated across multiple forms. See *How to Reduce Code Duplication with "inherit\_data"*.

When a field has the `inherit_data` option set, it uses the data of the parent form as is. This means that *Data Transformers* won't be applied to that field.

## invalid\_message

**type:** string **default:** This value is not valid

This is the validation error message that's used if the data entered into this field doesn't make sense (i.e. fails validation).

This might happen, for example, if the user enters a nonsense string into a *TimeType* field that cannot be converted into a real time or if the user enters a string (e.g. **apple**) into a number field.

Normal (business logic) validation (such as when setting a minimum length for a field) should be set using validation messages with your validation rules (reference).

## invalid\_message\_parameters

**type:** array **default:** array()

When setting the `invalid_message` option, you may need to include some variables in the string. This can be done by adding placeholders to that option and including the variables in this option:

```
Listing 45-9 1 $builder->add('some_field', SomeFormType::class, array(  
2     // ...  
3     'invalid_message' => 'You entered an invalid value, it should include %num% letters',  
4     'invalid_message_parameters' => array('%num%' => 6),  
5 ));
```

## label\_attr

**type:** array **default:** array()

Sets the HTML attributes for the `<label>` element, which will be used when rendering the label for the field. It's an associative array with HTML attribute as a key. This attributes can also be directly set inside the template:

```
Listing 45-10 1 {{ form_label(form.name, 'Your name', {  
2     'label_attr': {'class': 'CUSTOM_LABEL_CLASS'}  
3 }) }}
```

## label\_format

**type:** string **default:** null

Configures the string used as the label of the field, in case the `label` option was not set. This is useful when using keyword translation messages.

If you're using keyword translation messages as labels, you often end up having multiple keyword messages for the same label (e.g. `profile_address_street`, `invoice_address_street`). This is because the label is build for each "path" to a field. To avoid duplicated keyword messages, you can configure the label format to a static value, like:

Listing 45-11

```
1 // ...
2 $profileFormBuilder->add('address', AddressType::class, array(
3     'label_format' => 'form.address.%name%',
4 ));
5
6 $invoiceFormBuilder->add('invoice', AddressType::class, array(
7     'label_format' => 'form.address.%name%',
8 ));
```

This option is inherited by the child types. With the code above, the label of the **street** field of both forms will use the **form.address.street** keyword message.

Two variables are available in the label format:

**%id%**

A unique identifier for the field, consisting of the complete path to the field and the field name (e.g. `profile_address_street`);

**%name%**

The field name (e.g. `street`).

The default value (`null`) results in a "humanized" version of the field name.

The **label\_format** option is evaluated in the form theme. Make sure to update your templates in case you *customized form theming*.

## mapped

**type:** boolean **default:** true

If you wish the field to be ignored when reading or writing to the object, you can set the **mapped** option to **false**.

## method

**type:** string **default:** POST

This option specifies the HTTP method used to submit the form's data. Its value is rendered as the **method** attribute of the **form** element and is used to decide whether to process the form submission in the **handleRequest()** method after submission. Possible values are:

- POST
- GET
- PUT
- DELETE
- PATCH

When the method is PUT, PATCH, or DELETE, Symfony will automatically render a **\_method** hidden field in your form. This is used to "fake" these HTTP methods, as they're not supported on standard browsers. This can be useful when using method routing requirements.

The PATCH method allows submitting partial data. In other words, if the submitted form data is missing certain fields, those will be ignored and the default values (if any) will be used. With all other HTTP methods, if the submitted form data is missing some fields, those fields are set to **null**.

## post\_max\_size\_message

**type:** string **default:** The uploaded file was too large. Please try to upload a smaller file.

This is the validation error message that's used if submitted POST form data exceeds `php.ini`'s `post_max_size` directive. The `{{ max }}` placeholder can be used to display the allowed size.

Validating the `post_max_size` only happens on the root form.

## property\_path

**type:** PropertyPathInterface|string|null **default:** null

Fields display a property value of the form's domain object by default. When the form is submitted, the submitted value is written back into the object.

If you want to override the property that a field reads from and writes to, you can set the `property_path` option. Its default value (`null`) will use the field's name as the property.

## required

**type:** boolean **default:** true

If true, an *HTML5 required attribute*<sup>4</sup> will be rendered. The corresponding `label` will also render with a `required` class.

This is superficial and independent from validation. At best, if you let Symfony guess your field type, then the value of this option will be guessed from your validation information.

The `required` option also affects how empty data for each field is handled. For more details, see the `empty_data` option.

## trim

**type:** boolean **default:** true

If true, the whitespace of the submitted string value will be stripped via the *trim*<sup>5</sup> function when the data is bound. This guarantees that if a value is submitted with extra whitespace, it will be removed before the value is merged back onto the underlying object.

## Inherited Options

The following options are defined in the *BaseType*<sup>6</sup> class. The `BaseType` class is the parent class for both the `form` type and the `ButtonType`, but it is not part of the form type tree (i.e. it cannot be used as a form type on its own).

---

4. <http://diveintohtml5.info/forms.html>

5. <https://secure.php.net/manual/en/function.trim.php>

6. <https://api.symfony.com/4.0/Symfony/Component/Form/Extension/Core/Type/BaseType.html>

## attr

**type:** array **default:** array()

If you want to add extra attributes to an HTML field representation you can use the **attr** option. It's an associative array with HTML attributes as keys. This can be useful when you need to set a custom class for some widget:

```
Listing 45-12 $builder->add('body', TextareaType::class, array(  
    'attr' => array('class' => 'tinymce'),  
));
```

## auto\_initialize

**type:** boolean **default:** true

An internal option: sets whether the form should be initialized automatically. For all fields, this option should only be **true** for root forms. You won't need to change this option and probably won't need to worry about it.

## block\_name

**type:** string **default:** the form's name (see Knowing which block to customize)

Allows you to override the block name used to render the form type. Useful for example if you have multiple instances of the same form and you need to personalize the rendering of the forms individually.

## disabled

**type:** boolean **default:** false

If you don't want a user to modify the value of a field, you can set the disabled option to true. Any submitted value will be ignored.

## label

**type:** string **default:** The label is "guessed" from the field name

Sets the label that will be used when rendering the field. Setting to false will suppress the label. The label can also be directly set inside the template:

```
Listing 45-13 1 {{ form_label(form.name, 'Your name') }}
```

## translation\_domain

**type:** string, null or false **default:** null

This is the translation domain that will be used for any label or option that is rendered for this field. Use **null** to reuse the translation domain of the parent form (or the default domain of the translator for the root form). Use **false** to disable translations.

## Chapter 46

# Validation Constraints Reference

The Validator is designed to validate objects against *constraints*. In real life, a constraint could be: "The cake must not be burned". In Symfony, constraints are similar: They are assertions that a condition is true.

## Supported Constraints

The following constraints are natively available in Symfony:

### Basic Constraints

These are the basic constraints: use them to assert very basic things about the value of properties or the return value of methods on your object.

- *NotBlank*
- *Blank*
- *NotNull*
- *IsNull*
- *IsTrue*
- *IsFalse*
- *Type*

### String Constraints

- *Email*
- *Length*
- *Url*
- *Regex*
- *Ip*
- *Uuid*

## Number Constraints

- *Range*

## Comparison Constraints

- *EqualTo*
- *NotEqualTo*
- *IdenticalTo*
- *NotIdenticalTo*
- *LessThan*
- *LessThanOrEqual*
- *GreaterThan*
- *GreaterThanOrEqual*

## Date Constraints

- *Date*
- *DateTime*
- *Time*

## Collection Constraints

- *Choice*
- *Collection*
- *Count*
- *UniqueEntity*
- *Language*
- *Locale*
- *Country*

## File Constraints

- *File*
- *Image*

## Financial and other Number Constraints

- *Bic*
- *CardScheme*
- *Currency*
- *Luhn*
- *Iban*
- *Isbn*
- *Issn*

## Other Constraints

- *Callback*
- *Expression*
- *All*
- *UserPassword*
- *Valid*

## Chapter 47

# NotBlank

Validates that a value is not blank - meaning not equal to a blank string, a blank array or `null`:

Listing 47-1

```
if (false === $value || (empty($value) && '0' !== $value)) {  
    // validation will fail  
}
```

To force that a value is simply not equal to `null`, see the *NotNull* constraint.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>NotBlank</i> <sup>1</sup>
Validator	<i>NotBlankValidator</i> <sup>2</sup>

## Basic Usage

If you wanted to ensure that the `firstName` property of an `Author` class were not blank, you could do the following:

Listing 47-2

```
1 // src/Entity/Author.php  
2 namespace App\Entity;  
3  
4 use Symfony\Component\Validator\Constraints as Assert;  
5  
6 class Author  
7 {  
8     /**  
9      * @Assert\NotBlank()  
10     */
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotBlank.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotBlankValidator.html>

```
11     protected $firstName;  
12 }
```

## Options

### message

**type:** string **default:** This value should not be blank.

This is the message that will be shown if the value is blank.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 48

# Blank

Validates that a value is blank - meaning equal to an empty string or `null`:

```
Listing 48-1 if ('' !== $value && null !== $value) {  
    // validation will fail  
}
```

To force that a value strictly be equal to `null`, see the *IsNull* constraint.

To force that a value is *not* blank, see *NotBlank*. But be careful as **NotBlank** is *not* strictly the opposite of **Blank**.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Blank</i> <sup>1</sup>
Validator	<i>BlankValidator</i> <sup>2</sup>

## Basic Usage

If, for some reason, you wanted to ensure that the `firstName` property of an **Author** class were blank, you could do the following:

```
Listing 48-2 1 // src/Entity/Author.php  
2 namespace App\Entity;  
3  
4 use Symfony\Component\Validator\Constraints as Assert;  
5  
6 class Author  
7 {
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Blank.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/BlankValidator.html>

```
8     /**
9     * @Assert\Blank()
10    */
11    protected $firstName;
12 }
```

## Options

### message

**type:** string **default:** This value should be blank.

This is the message that will be shown if the value is not blank.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 49

# NotNull

Validates that a value is not strictly equal to `null`. To ensure that a value is simply not blank (not a blank string), see the *NotBlank* constraint.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>NotNull</i> <sup>1</sup>
Validator	<i>NotNullValidator</i> <sup>2</sup>

## Basic Usage

If you wanted to ensure that the `firstName` property of an `Author` class were not strictly equal to `null`, you would:

Listing 49-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\NotNull()
10     */
11     protected $firstName;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotNull.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotNullValidator.html>

# Options

## message

**type:** string **default:** This value should not be null.

This is the message that will be shown if the value is `null`.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 50

# IsNull

Validates that a value is exactly equal to **null**. To force that a property is simply blank (blank string or **null**), see the *Blank* constraint. To ensure that a property is not null, see *NotNull*.

Also see *NotNull*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>IsNull</i> <sup>1</sup>
Validator	<i>IsNullValidator</i> <sup>2</sup>

## Basic Usage

If, for some reason, you wanted to ensure that the `firstName` property of an `Author` class exactly equal to **null**, you could do the following:

```
Listing 50-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\IsNull()
10     */
11     protected $firstName;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IsNull.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IsNullValidator.html>

# Options

## message

**type:** string **default:** This value should be null.

This is the message that will be shown if the value is not `null`.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 51

# IsTrue

Validates that a value is **true**. Specifically, this checks to see if the value is exactly **true**, exactly the integer **1**, or exactly the string **"1"**.

Also see *IsFalse*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>True</i> <sup>1</sup>
Validator	<i>TrueValidator</i> <sup>2</sup>

## Basic Usage

This constraint can be applied to properties (e.g. a **termsAccepted** property on a registration model) or to a "getter" method. It's most powerful in the latter case, where you can assert that a method returns a true value. For example, suppose you have the following method:

Listing 51-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 class Author
5 {
6     protected $token;
7
8     public function isTokenValid()
9     {
10         return $this->token == $this->generateToken();
11     }
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/True.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/TrueValidator.html>

Then you can constrain this method with `IsTrue`.

```
Listing 51-2 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     protected $token;
9
10    /**
11     * @Assert\IsTrue(message="The token is invalid")
12     */
13    public function isValid()
14    {
15        return $this->token == $this->generateToken();
16    }
17 }
```

If the `isValid()` returns false, the validation will fail.

## Options

### message

**type:** string **default:** This value should be true.

This message is shown if the underlying data is not true.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 52

# IsFalse

Validates that a value is **false**. Specifically, this checks to see if the value is exactly **false**, exactly the integer **0**, or exactly the string **"0"**.

Also see *IsTrue*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>IsFalse</i> <sup>1</sup>
Validator	<i>IsFalseValidator</i> <sup>2</sup>

## Basic Usage

The **IsFalse** constraint can be applied to a property or a "getter" method, but is most commonly useful in the latter case. For example, suppose that you want to guarantee that some **state** property is *not* in a dynamic **invalidStates** array. First, you'd create a "getter" method:

```
Listing 52-1 1 protected $state;
2
3 protected $invalidStates = array();
4
5 public function isStateInvalid()
6 {
7     return in_array($this->state, $this->invalidStates);
8 }
```

In this case, the underlying object is only valid if the **isStateInvalid()** method returns **false**:

Listing 52-2

- 
1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IsFalse.html>
  2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IsFalseValidator.html>

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\IsFalse(
10     *     message = "You've entered an invalid state."
11     * )
12     */
13     public function isStateInvalid()
14     {
15         // ...
16     }
17 }

```

## Options

### message

**type:** string **default:** This value should be false.

This message is shown if the underlying data is not false.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 53

# Type

Validates that a value is of a specific data type. For example, if a variable should be an array, you can use this constraint with the **array** type option to validate this.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• type</li><li>• message</li><li>• payload</li></ul>
Class	<i>Type</i> <sup>1</sup>
Validator	<i>TypeValidator</i> <sup>2</sup>

## Basic Usage

This will check if **firstName** is of type **string** and that **age** is an **integer**.

Listing 53-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Type("string")
10     */
11     protected $firstName;
12
13     /**
14      * @Assert\Type(
15      *     type="integer",
16      *     message="The value {{ value }} is not a valid {{ type }}."
17     )
18     protected $age;
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Type.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/TypeValidator.html>

```

17     * )
18     */
19     protected $age;
20 }

```

## Options

type

**type:** `string` [default option]

This required option is the fully qualified class name or one of the PHP datatypes as determined by PHP's `is_()` functions.

- `array`<sup>3</sup>
- `bool`<sup>4</sup>
- `callable`<sup>5</sup>
- `float`<sup>6</sup>
- `double`<sup>7</sup>
- `int`<sup>8</sup>
- `integer`<sup>9</sup>
- `long`<sup>10</sup>
- `null`<sup>11</sup>
- `numeric`<sup>12</sup>
- `object`<sup>13</sup>
- `real`<sup>14</sup>
- `resource`<sup>15</sup>
- `scalar`<sup>16</sup>
- `string`<sup>17</sup>

Also, you can use `ctype_()` functions from corresponding *built-in PHP extension*<sup>18</sup>. Consider a list of *ctype functions*<sup>19</sup>:

- `alnum`<sup>20</sup>
- `alpha`<sup>21</sup>
- `cntrl`<sup>22</sup>
- `digit`<sup>23</sup>
- `graph`<sup>24</sup>
- `lower`<sup>25</sup>

22. <https://secure.php.net/manual/en/function.ctype-cntrl.php>  
23. <https://secure.php.net/manual/en/function.ctype-digit.php>  
24. <https://secure.php.net/manual/en/function.ctype-graph.php>

- *print*<sup>26</sup>
- *punct*<sup>27</sup>
- *space*<sup>28</sup>
- *upper*<sup>29</sup>
- *xdigit*<sup>30</sup>

Make sure that the proper *locale*<sup>31</sup> is set before using one of these.

### message

**type:** string **default:** This value should be of type {{ type }}.

The message if the underlying data is not of the given type.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 54

# Email

Validates that a value is a valid email address. The underlying value is cast to a string before being validated.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• strict</li><li>• message</li><li>• checkMX</li><li>• checkHost</li><li>• payload</li></ul>
Class	<i>Email</i> <sup>1</sup>
Validator	<i>EmailValidator</i> <sup>2</sup>

## Basic Usage

```
Listing 54-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Email(
10     *     message = "The email '{{ value }}' is not a valid email.",
11     *     checkMX = true
12     * )
13     */
14     protected $email;
15 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Email.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/EmailValidator.html>

# Options

## strict

**type:** boolean **default:** false

When false, the email will be validated against a simple regular expression. If true, then the *egulias/email-validator*<sup>3</sup> library is required to perform an RFC compliant validation.

## message

**type:** string **default:** This value is not a valid email address.

This message is shown if the underlying data is not a valid email address.

## checkMX

**type:** boolean **default:** false

If true, then the *checkdnsrr*<sup>4</sup> PHP function will be used to check the validity of the MX record of the host of the given email.

## checkHost

**type:** boolean **default:** false

If true, then the *checkdnsrr*<sup>5</sup> PHP function will be used to check the validity of the MX *or* the A *or* the AAAA record of the host of the given email.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

3. <https://packagist.org/packages/egulias/email-validator>

4. <https://secure.php.net/manual/en/function.checkdnsrr.php>

5. <https://secure.php.net/manual/en/function.checkdnsrr.php>

## Chapter 55

# Length

Validates that a given string length is *between* some minimum and maximum value.

`null` and empty strings are not handled by this constraint. You need to also add the *NotBlank* or *NotNull* constraints to validate against these.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• min</li><li>• max</li><li>• charset</li><li>• minMessage</li><li>• maxMessage</li><li>• exactMessage</li><li>• payload</li></ul>
Class	<i>Length</i> <sup>1</sup>
Validator	<i>LengthValidator</i> <sup>2</sup>

## Basic Usage

To verify that the `firstName` field length of a class is between "2" and "50", you might add the following:

```
Listing 55-1 1 // src/Entity/Participant.php
              2 namespace App\Entity;
              3
              4 use Symfony\Component\Validator\Constraints as Assert;
              5
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Length.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LengthValidator.html>

```

6 class Participant
7 {
8     /**
9     * @Assert\Length(
10    *     min = 2,
11    *     max = 50,
12    *     minMessage = "Your first name must be at least {{ limit }} characters long",
13    *     maxMessage = "Your first name cannot be longer than {{ limit }} characters"
14    * )
15    */
16    protected $firstName;
17 }

```

## Options

### min

#### type: integer

This required option is the "min" length value. Validation will fail if the given value's length is **less** than this min value.

It is important to notice that NULL values and empty strings are considered valid no matter if the constraint required a minimum length. Validators are triggered only if the value is not blank.

### max

#### type: integer

This required option is the "max" length value. Validation will fail if the given value's length is **greater** than this max value.

### charset

#### type: string default: UTF-8

The charset to be used when computing value's length. The *grapheme\_strlen*<sup>3</sup> PHP function is used if available. If not, the *mb\_strlen*<sup>4</sup> PHP function is used if available. If neither are available, the *strlen*<sup>5</sup> PHP function is used.

### minMessage

**type: string default:** This value is too short. It should have {{ limit }} characters or more.

The message that will be shown if the underlying value's length is less than the min option.

### maxMessage

**type: string default:** This value is too long. It should have {{ limit }} characters or less.

The message that will be shown if the underlying value's length is more than the max option.

---

3. <https://secure.php.net/manual/en/function.grapheme-strlen.php>

4. <https://secure.php.net/manual/en/function.mb-strlen.php>

5. <https://secure.php.net/manual/en/function strlen.php>

## exactMessage

**type:** string **default:** This value should have exactly `{{ limit }}` characters.

The message that will be shown if min and max values are equal and the underlying value's length is not exactly this value.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 56

# Url

Validates that a value is a valid URL string.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• protocols</li><li>• payload</li><li>• checkDNS</li><li>• dnsMessage</li></ul>
Class	<i>Url</i> <sup>1</sup>
Validator	<i>UrlValidator</i> <sup>2</sup>

## Basic Usage

Listing 56-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Url()
10     */
11     protected $bioUrl;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Url.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/UrlValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid URL.

This message is shown if the URL is invalid.

```
Listing 56-2 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Url(
10     *     message = "The url '{{ value }}' is not a valid url",
11     * )
12     */
13     protected $bioUrl;
14 }
```

## protocols

**type:** array **default:** array('http', 'https')

The protocols considered to be valid for the URL. For example, if you also consider the `ftp://` type URLs to be valid, redefine the `protocols` array, listing `http`, `https`, and also `ftp`.

```
Listing 56-3 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Url(
10     *     protocols = {"http", "https", "ftp"}
11     * )
12     */
13     protected $bioUrl;
14 }
```

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## checkDNS

**type:** boolean **default:** false

By default, this constraint just validates the syntax of the given URL. If you also need to check whether the associated host exists, set the `checkDNS` option to the value of any of the `CHECK_DNS_TYPE_*` constants in the `Url` class:

```
Listing 56-4 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Url(
10     *     checkDNS = "ANY"
11     * )
12     */
13     protected $bioUrl;
14 }
```

This option uses the `checkdnsrr`<sup>4</sup> PHP function to check the validity of the DNS record corresponding to the host associated with the given URL.

## dnsMessage

**type:** string **default:** The host could not be resolved.

This message is shown when the `checkDNS` option is set to `true` and the DNS check failed.

```
Listing 56-5 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Url(
10     *     dnsMessage = "The host '{{ value }}' could not be resolved."
11     * )
12     */
13     protected $bioUrl;
14 }
```

- 
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Url.html>
  4. <https://secure.php.net/manual/en/function.checkdnsrr.php>

## Chapter 57

# Regex

Validates that a value matches a regular expression.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• pattern</li><li>• htmlPattern</li><li>• match</li><li>• message</li><li>• payload</li></ul>
Class	<i>Regex</i> <sup>1</sup>
Validator	<i>RegexValidator</i> <sup>2</sup>

## Basic Usage

Suppose you have a **description** field and you want to verify that it begins with a valid word character. The regular expression to test for this would be `/^\w+/,` indicating that you're looking for at least one or more word characters at the beginning of your string:

```
Listing 57-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Regex("/^\w+/")
10    */
11    protected $description;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Regex.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/RegexValidator.html>

Alternatively, you can set the match option to `false` in order to assert that a given string does *not* match. In the following example, you'll assert that the `firstName` field does not contain any numbers and give it a custom message:

```
Listing 57-2 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Regex(
10      *     pattern="\d/",
11      *     match=false,
12      *     message="Your name cannot contain a number"
13      * )
14      */
15     protected $firstName;
16 }
```

## Options

### pattern

**type:** string [default option]

This required option is the regular expression pattern that the input will be matched against. By default, this validator will fail if the input string does *not* match this regular expression (via the `preg_match`<sup>3</sup> PHP function). However, if `match` is set to `false`, then validation will fail if the input string *does* match this pattern.

### htmlPattern

**type:** string | **boolean default:** null

This option specifies the pattern to use in the HTML5 `pattern` attribute. You usually don't need to specify this option because by default, the constraint will convert the pattern given in the `pattern` option into an HTML5 compatible pattern. This means that the delimiters are removed (e.g. `/[a-z]+/` becomes `[a-z]+`).

However, there are some other incompatibilities between both patterns which cannot be fixed by the constraint. For instance, the HTML5 `pattern` attribute does not support flags. If you have a pattern like `/[a-z]+/i`, you need to specify the HTML5 compatible pattern in the `htmlPattern` option:

```
Listing 57-3 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Regex(
10      *     pattern = "/^[a-z]+$/i",
11      *     htmlPattern = "[a-zA-Z]+$"
12      * )
13      */
```

---

3. <https://secure.php.net/manual/en/function.preg-match.php>

```
14     protected $name;  
15 }
```

Setting `htmlPattern` to false will disable client side validation.

## match

**type:** boolean **default:** true

If **true** (or not set), this validator will pass if the given string matches the given pattern regular expression. However, when this option is set to **false**, the opposite will occur: validation will pass only if the given string does **not** match the pattern regular expression.

## message

**type:** string **default:** This value is not valid.

This is the message that will be shown if this validator fails.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 58

# Ip

Validates that a value is a valid IP address. By default, this will validate the value as IPv4, but a number of different options exist to validate as IPv6 and many other combinations.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• version</li><li>• message</li><li>• payload</li></ul>
Class	<i>Ip</i> <sup>1</sup>
Validator	<i>IpValidator</i> <sup>2</sup>

## Basic Usage

Listing 58-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Ip
10     */
11     protected $ipAddress;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Ip.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IpValidator.html>

# Options

## version

**type:** string **default:** 4

This determines exactly *how* the IP address is validated and can take one of a variety of different values:

### All ranges

4

Validates for IPv4 addresses

6

Validates for IPv6 addresses

all

Validates all IP formats

### No private ranges

4\_no\_priv

Validates for IPv4 but without private IP ranges

6\_no\_priv

Validates for IPv6 but without private IP ranges

all\_no\_priv

Validates for all IP formats but without private IP ranges

### No reserved ranges

4\_no\_res

Validates for IPv4 but without reserved IP ranges

6\_no\_res

Validates for IPv6 but without reserved IP ranges

all\_no\_res

Validates for all IP formats but without reserved IP ranges

### Only public ranges

4\_public

Validates for IPv4 but without private and reserved ranges

6\_public

Validates for IPv6 but without private and reserved ranges

all\_public

Validates for all IP formats but without private and reserved ranges

## message

**type:** string **default:** This is not a valid IP address.

This message is shown if the string is not a valid IP address.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 59

# Uuid

Validates that a value is a valid *Universally unique identifier (UUID)*<sup>1</sup> per *RFC 4122*<sup>2</sup>. By default, this will validate the format according to the RFC's guidelines, but this can be relaxed to accept non-standard UUIDs that other systems (like PostgreSQL) accept. UUID versions can also be restricted using a whitelist.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• strict</li><li>• versions</li><li>• payload</li></ul>
Class	<i>Uuid</i> <sup>3</sup>
Validator	<i>UuidValidator</i> <sup>4</sup>

## Basic Usage

Listing 59-1

```
1 # config/validator/validation.yaml
2 App\Entity\File:
3   properties:
4     identifier:
5       - Uuid: ~
```

---

1. [http://en.wikipedia.org/wiki/Universally\\_unique\\_identifier](http://en.wikipedia.org/wiki/Universally_unique_identifier)  
2. <http://tools.ietf.org/html/rfc4122>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Uuid.html>  
4. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/UuidValidator.html>

# Options

## message

**type:** string **default:** This is not a valid UUID.

This message is shown if the string is not a valid UUID.

## strict

**type:** boolean **default:** true

If this option is set to **true** the constraint will check if the UUID is formatted per the RFC's input format rules: `216fff40-98d9-11e3-a5e2-0800200c9a66`. Setting this to **false** will allow alternate input formats like:

- `216f-ff40-98d9-11e3-a5e2-0800-200c-9a66`
- `{216fff40-98d9-11e3-a5e2-0800200c9a66}`
- `216fff4098d911e3a5e20800200c9a66`

## versions

**type:** int[] **default:** [1,2,3,4,5]

This option can be used to only allow specific *UUID versions*<sup>5</sup>. Valid versions are 1 - 5. The following PHP constants can also be used:

- `Uuid::V1_MAC`
- `Uuid::V2_DCE`
- `Uuid::V3_MD5`
- `Uuid::V4_RANDOM`
- `Uuid::V5_SHA1`

All five versions are allowed by default.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

5. [http://en.wikipedia.org/wiki/Universally\\_unique\\_identifier#Variants\\_and\\_versions](http://en.wikipedia.org/wiki/Universally_unique_identifier#Variants_and_versions)

## Chapter 60

# Range

Validates that a given number is *between* some minimum and maximum number.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• min</li><li>• max</li><li>• minMessage</li><li>• maxMessage</li><li>• invalidMessage</li><li>• payload</li></ul>
Class	<i>Range</i> <sup>1</sup>
Validator	<i>RangeValidator</i> <sup>2</sup>

## Basic Usage

To verify that the "height" field of a class is between "120" and "180", you might add the following:

```
Listing 60-1 1 // src/Entity/Participant.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Participant
7 {
8     /**
9      * @Assert\Range(
10     *     min = 120,
11     *     max = 180,
12     *     minMessage = "You must be at least {{ limit }}cm tall to enter",
13     *     maxMessage = "You cannot be taller than {{ limit }}cm to enter"
14     * )
```

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Range.html>

2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/RangeValidator.html>

```

15     */
16     protected $height;
17 }

```

## Date Ranges

This constraint can be used to compare `DateTime` objects against date ranges. The minimum and maximum date of the range should be given as any date string *accepted by the `DateTime` constructor*<sup>3</sup>. For example, you could check that a date must lie within the current year like this:

Listing 60-2

```

1 // src/Entity/Event.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Event
7 {
8     /**
9      * @Assert\Range(
10     *     min = "first day of January",
11     *     max = "first day of January next year"
12     * )
13     */
14     protected $startDate;
15 }

```

Be aware that PHP will use the server's configured timezone to interpret these dates. If you want to fix the timezone, append it to the date string:

Listing 60-3

```

1 // src/Entity/Event.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Event
7 {
8     /**
9      * @Assert\Range(
10     *     min = "first day of January UTC",
11     *     max = "first day of January next year UTC"
12     * )
13     */
14     protected $startDate;
15 }

```

The `DateTime` class also accepts relative dates or times. For example, you can check that a delivery date starts within the next five hours like this:

Listing 60-4

```

1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9      * @Assert\Range(
10     *     min = "now",
11     *     max = "+5 hours"
12     * )
13     */

```

---

3. <https://php.net/manual/en/datetime.formats.php>

```
14     protected $deliveryDate;  
15 }
```

## Options

### min

**type:** integer

This required option is the "min" value. Validation will fail if the given value is **less** than this min value.

### max

**type:** integer

This required option is the "max" value. Validation will fail if the given value is **greater** than this max value.

### minMessage

**type:** string **default:** This value should be {{ limit }} or more.

The message that will be shown if the underlying value is less than the min option.

### maxMessage

**type:** string **default:** This value should be {{ limit }} or less.

The message that will be shown if the underlying value is more than the max option.

### invalidMessage

**type:** string **default:** This value should be a valid number.

The message that will be shown if the underlying value is not a number (per the *is\_numeric*<sup>4</sup> PHP function).

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

4. <https://php.net/manual/en/function.is-numeric.php>

## Chapter 61

# EqualTo

Validates that a value is equal to another value, defined in the options. To force that a value is *not* equal, see *NotEqualTo*.

This constraint compares using `==`, so `3` and `"3"` are considered equal. Use *IdenticalTo* to compare with `===`.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>EqualTo</i> <sup>1</sup>
Validator	<i>EqualToValidator</i> <sup>2</sup>

## Basic Usage

If you want to ensure that the `firstName` of a `Person` class is equal to `Mary` and that the `age` is `20`, you could do the following:

```
Listing 61-1 1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/EqualTo.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/EqualToValidator.html>

```

9      * @Assert\EqualTo("Mary")
10     */
11     protected $firstName;
12
13     /**
14     * @Assert\EqualTo(
15     *     value = 20
16     * )
17     */
18     protected $age;
19 }

```

## Options

### value

**type:** mixed [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

### message

**type:** string **default:** This value should be equal to {{ compared\_value }}.

This is the message that will be shown if the value is not equal.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

### propertyPath

**type:** string

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 62

# NotEqualTo

Validates that a value is **not** equal to another value, defined in the options. To force that a value is equal, see *EqualTo*.

This constraint compares using `!=`, so `3` and `"3"` are considered equal. Use *NotIdenticalTo* to compare with `!==`.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>NotEqualTo</i> <sup>1</sup>
Validator	<i>NotEqualToValidator</i> <sup>2</sup>

## Basic Usage

If you want to ensure that the `firstName` of a `Person` is not equal to `Mary` and that the `age` of a `Person` class is not `15`, you could do the following:

```
Listing 62-1 1 // src/Entity/Person.php
              2 namespace App\Entity;
              3
              4 use Symfony\Component\Validator\Constraints as Assert;
              5
              6 class Person
              7 {
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotEqualTo.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotEqualToValidator.html>

```

8      /**
9       * @Assert\NotEqualTo("Mary")
10     */
11     protected $firstName;
12
13     /**
14     * @Assert\NotEqualTo(
15     *     value = 15
16     * )
17     */
18     protected $age;
19 }

```

## Options

### value

**type:** `mixed` [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

### message

**type:** `string` **default:** This value should not be equal to {{ compared\_value }}.

This is the message that will be shown if the value is equal.

### payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

### propertyPath

**type:** `string`

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 63

# IdenticalTo

Validates that a value is identical to another value, defined in the options. To force that a value is *not* identical, see *NotIdenticalTo*.

This constraint compares using `===`, so `3` and `"3"` are *not* considered equal. Use *EqualTo* to compare with `==`.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>IdenticalTo</i> <sup>1</sup>
Validator	<i>IdenticalToValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- `firstName` of `Person` class is equal to `Mary` *and* is a string
- `age` is equal to `20` *and* is of type integer

Listing 63-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IdenticalTo.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IdenticalToValidator.html>

```

6 class Person
7 {
8     /**
9      * @Assert\IdenticalTo("Mary")
10     */
11     protected $firstName;
12
13     /**
14      * @Assert\IdenticalTo(
15      *     value = 20
16      * )
17     */
18     protected $age;
19 }

```

## Options

### value

**type:** mixed [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

### message

**type:** string **default:** This value should be identical to {{ compared\_value\_type }} {{ compared\_value }}.

This is the message that will be shown if the value is not identical.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

### propertyPath

**type:** string

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 64

# NotIdenticalTo

Validates that a value is **not** identical to another value, defined in the options. To force that a value is identical, see *IdenticalTo*.

This constraint compares using `!==`, so `3` and `"3"` are considered not equal. Use *NotEqualTo* to compare with `!=`.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>NotIdenticalTo</i> <sup>1</sup>
Validator	<i>NotIdenticalToValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- `firstName` of `Person` is not equal to `Mary` *or* not of the same type
- `age` of `Person` class is not equal to `15` *or* not of the same type

Listing 64-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
```

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotIdenticalTo.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/NotIdenticalToValidator.html>

```

6 class Person
7 {
8     /**
9     * @Assert\NotIdenticalTo("Mary")
10    */
11    protected $firstName;
12
13    /**
14    * @Assert\NotIdenticalTo(
15    *     value = 15
16    * )
17    */
18    protected $age;
19 }

```

## Options

### value

**type:** mixed [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

### message

**type:** string **default:** This value should not be identical to {{ compared\_value\_type }} {{ compared\_value }}.

This is the message that will be shown if the value is identical.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

### propertyPath

**type:** string

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 65

# LessThan

Validates that a value is less than another value, defined in the options. To force that a value is less than or equal to another value, see *LessThanOrEqual*. To force a value is greater than another value, see *GreaterThan*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>LessThan</i> <sup>1</sup>
Validator	<i>LessThanValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- the number of siblings of a Person is less than 5
- age is less than 80

Listing 65-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8
9     /**
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LessThan.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LessThanValidator.html>

```

10     * @Assert\LessThan(5)
11     */
12     protected $siblings;
13
14     /**
15     * @Assert\LessThan(
16     *     value = 80
17     * )
18     */
19     protected $age;
20 }

```

## Comparing Dates

This constraint can be used to compare `DateTime` objects against any date string *accepted by the `DateTime` constructor*<sup>3</sup>. For example, you could check that a date must be in the past like this:

Listing 65-2

```

1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThan("today")
10    */
11    protected $dateOfBirth;
12 }

```

Be aware that PHP will use the server's configured timezone to interpret these dates. If you want to fix the timezone, append it to the date string:

Listing 65-3

```

1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThan("today UTC")
10    */
11    protected $dateOfBirth;
12 }

```

The `DateTime` class also accepts relative dates or times. For example, you can check that a person must be at least 18 years old like this:

Listing 65-4

```

1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThan("-18 years")
10    */
11    protected $dateOfBirth;
12 }

```

---

3. <https://php.net/manual/en/datetime.formats.php>

# Options

## value

**type:** `mixed` [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

## message

**type:** `string` **default:** `This value should be less than {{ compared_value }}`.

This is the message that will be shown if the value is not less than the comparison value.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## propertyPath

**type:** `string`

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 66

# LessThanOrEqual

Validates that a value is less than or equal to another value, defined in the options. To force that a value is less than another value, see *LessThan*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>LessThanOrEqual</i> <sup>1</sup>
Validator	<i>LessThanOrEqualValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- the number of `siblings` of a `Person` is less than or equal to 5
- the `age` is less than or equal to 80

Listing 66-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9      * @Assert\LessThanOrEqual(5)
10     */
11     protected $siblings;
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LessThanOrEqual.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LessThanOrEqualValidator.html>

```

12
13     /**
14     * @Assert\LessThanOrEqual(
15     *     value = 80
16     * )
17     */
18     protected $age;
19 }

```

## Comparing Dates

This constraint can be used to compare `DateTime` objects against any date string *accepted by the `DateTime` constructor*<sup>3</sup>. For example, you could check that a date must be today or in the past like this:

```

Listing 66-2 1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThanOrEqual("today")
10    */
11    protected $age;
12 }

```

Be aware that PHP will use the server's configured timezone to interpret these dates. If you want to fix the timezone, append it to the date string:

```

Listing 66-3 1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThanOrEqual("today UTC")
10    */
11    protected $age;
12 }

```

The `DateTime` class also accepts relative dates or times. For example, you can check that a person must be at least 18 years old like this:

```

Listing 66-4 1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9     * @Assert\LessThanOrEqual("-18 years")
10    */
11    protected $age;
12 }

```

---

3. <https://php.net/manual/en/datetime.formats.php>

# Options

## value

**type:** `mixed` [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

## message

**type:** `string` **default:** `This value should be less than or equal to {{ compared_value }}`.

This is the message that will be shown if the value is not less than or equal to the comparison value.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## propertyPath

**type:** `string`

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 67

# GreaterThan

Validates that a value is greater than another value, defined in the options. To force that a value is greater than or equal to another value, see *GreaterThanOrEqual*. To force a value is less than another value, see *LessThan*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>GreaterThan</i> <sup>1</sup>
Validator	<i>GreaterThanValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- the number of siblings of a Person is greater than 5
- the age of a Person class is greater than 18

Listing 67-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8
9     /**
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/GreaterThan.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/GreaterThanValidator.html>

```

10     * @Assert\GreaterThan(5)
11     */
12     protected $siblings;
13
14     /**
15     * @Assert\GreaterThan(
16     *     value = 18
17     * )
18     */
19     protected $age;
20 }

```

## Comparing Dates

This constraint can be used to compare `DateTime` objects against any date string *accepted by the `DateTime` constructor*<sup>3</sup>. For example, you could check that a date must at least be the next day:

Listing 67-2

```

1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThan("today")
10    */
11    protected $deliveryDate;
12 }

```

Be aware that PHP will use the server's configured timezone to interpret these dates. If you want to fix the timezone, append it to the date string:

Listing 67-3

```

1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThan("today UTC")
10    */
11    protected $deliveryDate;
12 }

```

The `DateTime` class also accepts relative dates or times. For example, you can check that the above delivery date starts at least five hours after the current time:

Listing 67-4

```

1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThan("+5 hours")
10    */
11    protected $deliveryDate;
12 }

```

---

3. <https://php.net/manual/en/datetime.formats.php>

# Options

## value

**type:** `mixed` [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

## message

**type:** `string` **default:** `This value should be greater than {{ compared_value }}`.

This is the message that will be shown if the value is not greater than the comparison value.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## propertyPath

**type:** `string`

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 68

# GreaterThanOrEqual

Validates that a value is greater than or equal to another value, defined in the options. To force that a value is greater than another value, see *GreaterThan*.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• value</li><li>• message</li><li>• payload</li><li>• propertyPath</li></ul>
Class	<i>GreaterThanOrEqual</i> <sup>1</sup>
Validator	<i>GreaterThanOrEqualValidator</i> <sup>2</sup>

## Basic Usage

The following constraints ensure that:

- the number of siblings of a *Person* is greater than or equal to 5
- the age of a *Person* class is greater than or equal to 18

Listing 68-1

```
1 // src/Entity/Person.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Person
7 {
8     /**
9      * @Assert\GreaterThanOrEqual(5)
10     */
11     protected $siblings;
```

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/GreaterThanOrEqual.html>

2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/GreaterThanOrEqualValidator.html>

```

12
13     /**
14     * @Assert\GreaterThanOrEqual(
15     *     value = 18
16     * )
17     */
18     protected $age;
19 }

```

## Comparing Dates

This constraint can be used to compare `DateTime` objects against any date string *accepted by the `DateTime` constructor*<sup>3</sup>. For example, you could check that a date must at least be the current day:

```

Listing 68-2 1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThanOrEqual("today")
10    */
11    protected $deliveryDate;
12 }

```

Be aware that PHP will use the server's configured timezone to interpret these dates. If you want to fix the timezone, append it to the date string:

```

Listing 68-3 1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThanOrEqual("today UTC")
10    */
11    protected $deliveryDate;
12 }

```

The `DateTime` class also accepts relative dates or times. For example, you can check that the above delivery date starts at least five hours after the current time:

```

Listing 68-4 1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9     * @Assert\GreaterThanOrEqual("+5 hours")
10    */
11    protected $deliveryDate;
12 }

```

---

3. <https://php.net/manual/en/datetime.formats.php>

# Options

## value

**type:** `mixed` [default option]

This option is required. It defines the value to compare to. It can be a string, number or object.

## message

**type:** `string` **default:** `This value should be greater than or equal to {{compared_value}}`.

This is the message that will be shown if the value is not greater than or equal to the comparison value.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## propertyPath

**type:** `string`

It defines the object property whose value is used to make the comparison.

For example, if you want to compare the `$endDate` property of some object with regard to the `$startDate` property of the same object, use `propertyPath="startDate"` in the comparison constraint of `$endDate`.

## Chapter 69

# Date

Validates that a value is a valid date, meaning either a **DateTime** object or a string (or an object that can be cast into a string) that follows a valid YYYY-MM-DD format.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Date</i> <sup>1</sup>
Validator	<i>DateValidator</i> <sup>2</sup>

## Basic Usage

```
Listing 69-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Date()
10     */
11     protected $birthday;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Date.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/DateValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid date.

This message is shown if the underlying data is not a valid date.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 70

# DateTime

Validates that a value is a valid "datetime", meaning either a **DateTime** object or a string (or an object that can be cast into a string) that follows a specific format.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• format</li><li>• message</li><li>• payload</li></ul>
Class	<i>DateTime</i> <sup>1</sup>
Validator	<i>DateTimeValidator</i> <sup>2</sup>

## Basic Usage

Listing 70-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\DateTime()
10     */
11     protected $createdAt;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/DateTime.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/DateTimeValidator.html>

# Options

## format

**type:** string **default:** Y-m-d H:i:s

This option allows to validate a custom date format. See `DateTime::createFromFormat()`<sup>3</sup> for formatting options.

## message

**type:** string **default:** This value is not a valid datetime.

This message is shown if the underlying data is not a valid datetime.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

3. <https://secure.php.net/manual/en/datetime.createfromformat.php>

## Chapter 71

# Time

Validates that a value is a valid time, meaning an object implementing `DateTimeInterface` or a string (or an object that can be cast into a string) that follows a valid `HH:MM:SS` format.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<code>Time</code> <sup>1</sup>
Validator	<code>TimeValidator</code> <sup>2</sup>

## Basic Usage

Suppose you have an `Event` class, with a `startAt` field that is the time of the day when the event starts:

```
Listing 71-1 1 // src/Entity/Event.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Event
7 {
8     /**
9      * @Assert\Time()
10     */
11     protected $startAt;
12 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Time.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/TimeValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid time.

This message is shown if the underlying data is not a valid time.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 72

# Choice

This constraint is used to ensure that the given value is one of a given set of *valid* choices. It can also be used to validate that each item in an array of items is one of those valid choices.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• choices</li><li>• callback</li><li>• multiple</li><li>• min</li><li>• max</li><li>• message</li><li>• multipleMessage</li><li>• minMessage</li><li>• maxMessage</li><li>• strict</li><li>• payload</li></ul>
Class	<i>Choice</i> <sup>1</sup>
Validator	<i>ChoiceValidator</i> <sup>2</sup>

## Basic Usage

The basic idea of this constraint is that you supply it with an array of valid values (this can be done in several ways) and it validates that the value of the given property exists in that array.

If your valid choice list is simple, you can pass them in directly via the choices option:

Listing 72-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Choice.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/ChoiceValidator.html>

```

4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Choice({"New York", "Berlin", "Tokyo"})
10    */
11    protected $city;
12
13    /**
14     * @Assert\Choice(choices={"fiction", "non-fiction"}, message="Choose a valid genre.")
15    */
16    protected $genre;
17 }

```

## Supplying the Choices with a Callback Function

You can also use a callback function to specify your options. This is useful if you want to keep your choices in some central location so that, for example, you can easily access those choices for validation or for building a select form element:

Listing 72-2

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 class Author
5 {
6     public static function getGenres()
7     {
8         return array('fiction', 'non-fiction');
9     }
10 }

```

You can pass the name of this method to the callback option of the **Choice** constraint.

Listing 72-3

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Choice(callback="getGenres")
10    */
11    protected $genre;
12 }

```

If the callback is stored in a different class and is static, for example **Util**, you can pass the class name and the method as an array.

Listing 72-4

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Choice(callback={"Util", "getGenres"})
10    */
11    protected $genre;
12 }

```

# Available Options

## choices

**type:** array [default option]

A required option (unless callback is specified) - this is the array of options that should be considered in the valid set. The input value will be matched against this array.

## callback

**type:** string|array|Closure

This is a callback method that can be used instead of the choices option to return the choices array. See [Supplying the Choices with a Callback Function](#) for details on its usage.

## multiple

**type:** boolean **default:** false

If this option is true, the input value is expected to be an array instead of a single, scalar value. The constraint will check that each value of the input array can be found in the array of valid choices. If even one of the input values cannot be found, the validation will fail.

## min

**type:** integer

If the **multiple** option is true, then you can use the **min** option to force at least XX number of values to be selected. For example, if **min** is 3, but the input array only contains 2 valid items, the validation will fail.

## max

**type:** integer

If the **multiple** option is true, then you can use the **max** option to force no more than XX number of values to be selected. For example, if **max** is 3, but the input array contains 4 valid items, the validation will fail.

## message

**type:** string **default:** The value you selected is not a valid choice.

This is the message that you will receive if the **multiple** option is set to **false** and the underlying value is not in the valid array of choices.

## multipleMessage

**type:** string **default:** One or more of the given values is invalid.

This is the message that you will receive if the **multiple** option is set to **true** and one of the values on the underlying array being checked is not in the array of valid choices.

## minMessage

**type:** string **default:** You must select at least {{ limit }} choices.

This is the validation error message that's displayed when the user chooses too few choices per the min option.

## maxMessage

**type:** string **default:** You must select at most {{ limit }} choices.

This is the validation error message that's displayed when the user chooses too many options per the max option.

## strict

**type:** boolean **default:** true

The validator will also check the type of the input value. Specifically, this value is passed to as the third argument to the PHP *in\_array*<sup>3</sup> method when checking to see if a value is in the valid choices array.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

3. <https://secure.php.net/manual/en/function.in-array.php>

## Chapter 73

# Collection

This constraint is used when the underlying data is a collection (i.e. an array or an object that implements **Traversable** and **ArrayAccess**), but you'd like to validate different keys of that collection in different ways. For example, you might validate the **email** key using the **Email** constraint and the **inventory** key of the collection with the **Range** constraint.

This constraint can also make sure that certain collection keys are present and that extra keys are not present.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• fields</li><li>• allowExtraFields</li><li>• extraFieldsMessage</li><li>• allowMissingFields</li><li>• missingFieldsMessage</li><li>• payload</li></ul>
Class	<i>Collection</i> <sup>1</sup>
Validator	<i>CollectionValidator</i> <sup>2</sup>

## Basic Usage

The **Collection** constraint allows you to validate the different keys of a collection individually. Take the following example:

Listing 73-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 class Author
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Collection.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CollectionValidator.html>

```

5 {
6     protected $profileData = array(
7         'personal_email' => '...',
8         'short_bio' => '...',
9     );
10
11     public function setProfileData($key, $value)
12     {
13         $this->profileData[$key] = $value;
14     }
15 }

```

To validate that the `personal_email` element of the `profileData` array property is a valid email address and that the `short_bio` element is not blank but is no longer than 100 characters in length, you would do the following:

Listing 73-2

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Collection(
10     *     fields = {
11     *         "personal_email" = @Assert\Email,
12     *         "short_bio" = {
13     *             @Assert\NotBlank(),
14     *             @Assert\Length(
15     *                 max = 100,
16     *                 maxMessage = "Your short bio is too long!"
17     *             )
18     *         }
19     *     },
20     *     allowMissingFields = true
21     * )
22     */
23     protected $profileData = array(
24         'personal_email' => '...',
25         'short_bio' => '...',
26     );
27 }

```

## Presence and Absence of Fields

By default, this constraint validates more than simply whether or not the individual fields in the collection pass their assigned constraints. In fact, if any keys of a collection are missing or if there are any unrecognized keys in the collection, validation errors will be thrown.

If you would like to allow for keys to be absent from the collection or if you would like "extra" keys to be allowed in the collection, you can modify the `allowMissingFields` and `allowExtraFields` options respectively. In the above example, the `allowMissingFields` option was set to `true`, meaning that if either of the `personal_email` or `short_bio` elements were missing from the `$profileData` property, no validation error would occur.

## Required and Optional Field Constraints

Constraints for fields within a collection can be wrapped in the `Required` or `Optional` constraint to control whether they should always be applied (`Required`) or only applied when the field is present (`Optional`).

For instance, if you want to require that the `personal_email` field of the `profileData` array is not blank and is a valid email but the `alternate_email` field is optional but must be a valid email if supplied, you can do the following:

```
Listing 73-3 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Collection(
10     *     fields={
11     *         "personal_email" = @Assert\Required({@Assert\NotBlank, @Assert\Email}),
12     *         "alternate_email" = @Assert\Optional(@Assert\Email)
13     *     }
14     * )
15     */
16     protected $profileData = array('personal_email');
17 }
```

Even without `allowMissingFields` set to true, you can now omit the `alternate_email` property completely from the `profileData` array, since it is `Optional`. However, if the `personal_email` field does not exist in the array, the `NotBlank` constraint will still be applied (since it is wrapped in `Required`) and you will receive a constraint violation.

## Options

### fields

**type:** array [default option]

This option is required and is an associative array defining all of the keys in the collection and, for each key, exactly which validator(s) should be executed against that element of the collection.

### allowExtraFields

**type:** boolean **default:** false

If this option is set to `false` and the underlying collection contains one or more elements that are not included in the `fields` option, a validation error will be returned. If set to `true`, extra fields are ok.

### extraFieldsMessage

**type:** string **default:** This field was not expected.

The message shown if `allowExtraFields` is false and an extra field is detected.

### allowMissingFields

**type:** boolean **default:** false

If this option is set to `false` and one or more fields from the `fields` option are not present in the underlying collection, a validation error will be returned. If set to `true`, it's ok if some fields in the `fields` option are not present in the underlying collection.

## missingFieldsMessage

**type:** string **default:** This field is missing.

The message shown if `allowMissingFields` is false and one or more fields are missing from the underlying collection.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 74

# Count

Validates that a given collection's (i.e. an array or an object that implements Countable) element count is *between* some minimum and maximum value.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• min</li><li>• max</li><li>• minMessage</li><li>• maxMessage</li><li>• exactMessage</li><li>• payload</li></ul>
Class	<code>Count</code> <sup>1</sup>
Validator	<code>CountValidator</code> <sup>2</sup>

## Basic Usage

To verify that the `emails` array field contains between 1 and 5 elements you might add the following:

```
Listing 74-1 1 // src/Entity/Participant.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Participant
7 {
8     /**
9      * @Assert\Count(
10     *     min = 1,
11     *     max = 5,
12     *     minMessage = "You must specify at least one email",
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Count.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CountValidator.html>

```
13     *      maxMessage = "You cannot specify more than {{ limit }} emails"
14     * )
15     */
16     protected $emails = array();
17 }
```

## Options

### min

#### **type:** integer

This required option is the "min" count value. Validation will fail if the given collection elements count is **less** than this min value.

### max

#### **type:** integer

This required option is the "max" count value. Validation will fail if the given collection elements count is **greater** than this max value.

### minMessage

**type:** string **default:** This collection should contain {{ limit }} elements or more.

The message that will be shown if the underlying collection elements count is less than the min option.

### maxMessage

**type:** string **default:** This collection should contain {{ limit }} elements or less.

The message that will be shown if the underlying collection elements count is more than the max option.

### exactMessage

**type:** string **default:** This collection should contain exactly {{ limit }} elements.

The message that will be shown if min and max values are equal and the underlying collection elements count is not exactly this value.

### payload

#### **type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 75

# UniqueEntity

Validates that a particular field (or fields) in a Doctrine entity is (are) unique. This is commonly used, for example, to prevent a new user to register using an email address that already exists in the system.

Applies to	class
Options	<ul style="list-style-type: none"><li>• fields</li><li>• message</li><li>• em</li><li>• repositoryMethod</li><li>• entityClass</li><li>• errorPath</li><li>• ignoreNull</li><li>• payload</li></ul>
Class	<i>UniqueEntity</i> <sup>1</sup>
Validator	<i>UniqueEntityValidator</i> <sup>2</sup>

## Basic Usage

Suppose you have a **User** entity that has an **email** field. You can use the **UniqueEntity** constraint to guarantee that the **email** field remains unique between all of the constraints in your user table:

Listing 75-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5 use Doctrine\ORM\Mapping as ORM;
6
7 // DON'T forget this use statement!!!
8 use Symfony\Bridge\Doctrine\Validator\Constraints\UniqueEntity;
```

1. <https://api.symfony.com/4.0/Symfony/Bridge/Doctrine/Validator/Constraints/UniqueEntity.html>

2. <https://api.symfony.com/4.0/Symfony/Bridge/Doctrine/Validator/Constraints/UniqueEntityValidator.html>

```

9
10 /**
11  * @ORM\Entity
12  * @UniqueEntity("email")
13  */
14 class Author
15 {
16     /**
17      * @var string $email
18      *
19      * @ORM\Column(name="email", type="string", length=255, unique=true)
20      * @AssertEmail()
21      */
22     protected $email;
23
24     // ...
25 }

```

## Options

### fields

**type:** array | string [default option]

This required option is the field (or list of fields) on which this entity should be unique. For example, if you specified both the **email** and **name** field in a single **UniqueEntity** constraint, then it would enforce that the combination value is unique (e.g. two users could have the same email, as long as they don't have the same name also).

If you need to require two fields to be individually unique (e.g. a unique **email** and a unique **username**), you use two **UniqueEntity** entries, each with a single field.

### message

**type:** string **default:** This value is already used.

The message that's displayed when this constraint fails. This message is always mapped to the first field causing the violation, even when using multiple fields in the constraint.

Messages can include the `{{ value }}` placeholder to display a string representation of the invalid entity. If the entity doesn't define the `__toString()` method, the following generic value will be used: `"Object of class __CLASS__ identified by <comma separated IDs>"`

### em

**type:** string

The name of the entity manager to use for making the query to determine the uniqueness. If it's left blank, the correct entity manager will be determined for this class. For that reason, this option should probably not need to be used.

### repositoryMethod

**type:** string **default:** findBy()

The name of the repository method to use for making the query to determine the uniqueness. If it's left blank, the `findBy()` method will be used. This method should return a countable result.

## entityClass

**type:** string

By default, the query performed to ensure the uniqueness uses the repository of the current class instance. However, in some cases, such as when using Doctrine inheritance mapping, you need to execute the query in a different repository. Use this option to define the fully-qualified class name (FQCN) of the Doctrine entity associated with the repository you want to use.

## errorPath

**type:** string **default:** The name of the first field in fields

If the entity violates the constraint the error message is bound to the first field in fields. If there is more than one field, you may want to map the error message to another field.

Consider this example:

```
Listing 75-2 1 // src/Entity/Service.php
2 namespace App\Entity;
3
4 use Doctrine\ORM\Mapping as ORM;
5 use Symfony\Bridge\Doctrine\Validator\Constraints\UniqueEntity;
6
7 /**
8  * @ORM\Entity
9  * @UniqueEntity(
10  *     fields={"host", "port"},
11  *     errorPath="port",
12  *     message="This port is already in use on that host."
13  * )
14 */
15 class Service
16 {
17     /**
18      * @ORM\ManyToOne(targetEntity="Host")
19      */
20     public $host;
21
22     /**
23      * @ORM\Column(type="integer")
24      */
25     public $port;
26 }
```

Now, the message would be bound to the **port** field with this configuration.

## ignoreNull

**type:** boolean **default:** true

If this option is set to **true**, then the constraint will allow multiple entities to have a **null** value for a field without failing validation. If set to **false**, only one **null** value is allowed - if a second entity also has a **null** value, validation would fail.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 76

# Language

Validates that a value is a valid language *Unicode language identifier* (e.g. `fr` or `zh-Hant`).

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Language</i> <sup>1</sup>
Validator	<i>LanguageValidator</i> <sup>2</sup>

## Basic Usage

Listing 76-1

```
1 // src/Entity/User.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class User
7 {
8     /**
9      * @Assert\Language()
10     */
11     protected $preferredLanguage;
12 }
```

2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LanguageValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid language.

This message is shown if the string is not a valid language code.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 77

# Locale

Validates that a value is a valid locale.

The "value" for each locale is either the two letter *ISO 639-1*<sup>1</sup> language code (e.g. `fr`), or the language code followed by an underscore (`_`), then the *ISO 3166-1 alpha-2*<sup>2</sup> country code (e.g. `fr_FR` for French/France).

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Locale</i> <sup>3</sup>
Validator	<i>LocaleValidator</i> <sup>4</sup>

## Basic Usage

```
Listing 77-1 1 // src/Entity/User.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class User
7 {
8     /**
9      * @Assert\Locale()
10     */
11     protected $locale;
12 }
```

  4. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LocaleValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid locale.

This message is shown if the string is not a valid locale.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 78

# Country

Validates that a value is a valid *ISO 3166-1 alpha-2*<sup>1</sup> country code.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Country</i> <sup>2</sup>
Validator	<i>CountryValidator</i> <sup>3</sup>

## Basic Usage

Listing 78-1

```
1 // src/Entity/User.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class User
7 {
8     /**
9      * @Assert\Country()
10     */
11     protected $country;
12 }
```

---

1. [https://en.wikipedia.org/wiki/ISO\\_3166-1#Current\\_codes](https://en.wikipedia.org/wiki/ISO_3166-1#Current_codes)  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Country.html>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CountryValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid country.

This message is shown if the string is not a valid country code.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 79

# File

Validates that a value is a valid "file", which can be one of the following:

- A string (or object with a `__toString()` method) path to an existing file;
- A valid *File*<sup>1</sup> object (including objects of class *UploadedFile*<sup>2</sup>).

This constraint is commonly used in forms with the *FileType* form field.

If the file you're validating is an image, try the *Image* constraint.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• <code>maxSize</code></li><li>• <code>binaryFormat</code></li><li>• <code>mimeTypes</code></li><li>• <code>maxSizeMessage</code></li><li>• <code>mimeTypesMessage</code></li><li>• <code>disallowEmptyMessage</code></li><li>• <code>notFoundMessage</code></li><li>• <code>notReadableMessage</code></li><li>• <code>uploadIniSizeErrorMessage</code></li><li>• <code>uploadFormSizeErrorMessage</code></li><li>• <code>uploadErrorMessage</code></li><li>• <code>payload</code></li></ul>
Class	<i>File</i> <sup>3</sup>
Validator	<i>FileValidator</i> <sup>4</sup>

1. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/File/File.html>

2. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/File/UploadedFile.html>

3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/File.html>

4. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/FileValidator.html>

## Basic Usage

This constraint is most commonly used on a property that will be rendered in a form as a *FileType* field. For example, suppose you're creating an author form where you can upload a "bio" PDF for the author. In your form, the `bioFile` property would be a `file` type. The `Author` class might look as follows:

```
Listing 79-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\HttpFoundation\File\File;
5
6 class Author
7 {
8     protected $bioFile;
9
10    public function setBioFile(File $file = null)
11    {
12        $this->bioFile = $file;
13    }
14
15    public function getBioFile()
16    {
17        return $this->bioFile;
18    }
19 }
```

To guarantee that the `bioFile` `File` object is valid and that it is below a certain file size and a valid PDF, add the following:

```
Listing 79-2 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\File(
10     *     maxSize = "1024k",
11     *     mimeTypes = {"application/pdf", "application/x-pdf"},
12     *     mimeTypesMessage = "Please upload a valid PDF"
13     * )
14     */
15    protected $bioFile;
16 }
```

The `bioFile` property is validated to guarantee that it is a real file. Its size and mime type are also validated because the appropriate options have been specified.

## Options

### maxSize

#### type: mixed

If set, the size of the underlying file must be below this file size in order to be valid. The size of the file can be given in one of the following formats:

Suffix	Unit Name	value	e.g.
	byte	1 byte	4096

Suffix	Unit Name	value	e.g.
k	kilobyte	1,000 bytes	200k
M	megabyte	1,000,000 bytes	2M
Ki	kibibyte	1,024 bytes	32Ki
Mi	mebibyte	1,048,576 bytes	8Mi

For more information about the difference between binary and SI prefixes, see *Wikipedia: Binary prefix*<sup>5</sup>.

## binaryFormat

**type:** boolean **default:** null

When **true**, the sizes will be displayed in messages with binary-prefixed units (KiB, MiB). When **false**, the sizes will be displayed with SI-prefixed units (kB, MB). When **null**, then the binaryFormat will be guessed from the value defined in the **maxSize** option.

For more information about the difference between binary and SI prefixes, see *Wikipedia: Binary prefix*<sup>6</sup>.

## mimeTypes

**type:** array or string

If set, the validator will check that the mime type of the underlying file is equal to the given mime type (if a string) or exists in the collection of given mime types (if an array).

You can find a list of existing mime types on the *IANA website*<sup>7</sup>.

## maxSizeMessage

**type:** string **default:** The file is too large ({{ size }} {{ suffix }}). Allowed maximum size is {{ limit }} {{ suffix }}.

The message displayed if the file is larger than the maxSize option.

## mimeTypesMessage

**type:** string **default:** The mime type of the file is invalid ({{ type }}). Allowed mime types are {{ types }}.

The message displayed if the mime type of the file is not a valid mime type per the mimeTypes option.

## disallowEmptyMessage

**type:** string **default:** An empty file is not allowed.

This constraint checks if the uploaded file is empty (i.e. 0 bytes). If it is, this message is displayed.

## notFoundMessage

**type:** string **default:** The file could not be found.

5. [http://en.wikipedia.org/wiki/Binary\\_prefix](http://en.wikipedia.org/wiki/Binary_prefix)

6. [http://en.wikipedia.org/wiki/Binary\\_prefix](http://en.wikipedia.org/wiki/Binary_prefix)

7. <http://www.iana.org/assignments/media-types/index.html>

The message displayed if no file can be found at the given path. This error is only likely if the underlying value is a string path, as a **File** object cannot be constructed with an invalid file path.

### notReadableMessage

**type:** string **default:** The file is not readable.

The message displayed if the file exists, but the PHP `is_readable()` function fails when passed the path to the file.

### uploadIniSizeErrorMessage

**type:** string **default:** The file is too large. Allowed maximum size is `{{ limit }}` `{{ suffix }}`.

The message that is displayed if the uploaded file is larger than the `upload_max_filesize` `php.ini` setting.

### uploadFormSizeErrorMessage

**type:** string **default:** The file is too large.

The message that is displayed if the uploaded file is larger than allowed by the HTML file input field.

### uploadErrorMessage

**type:** string **default:** The file could not be uploaded.

The message that is displayed if the uploaded file could not be uploaded for some unknown reason, such as the file upload failed or it couldn't be written to disk.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 80

# Image

The `Image` constraint works exactly like the `File` constraint, except that its `mimeType`s and `mimeTypeMessage` options are automatically setup to work for image files specifically.

Additionally it has options so you can validate against the width and height of the image.

See the `File` constraint for the bulk of the documentation on this constraint.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• <code>mimeType</code>s</li><li>• <code>minWidth</code></li><li>• <code>maxWidth</code></li><li>• <code>maxHeight</code></li><li>• <code>minHeight</code></li><li>• <code>maxRatio</code></li><li>• <code>minRatio</code></li><li>• <code>allowSquare</code></li><li>• <code>allowLandscape</code></li><li>• <code>allowPortrait</code></li><li>• <code>detectCorrupted</code></li><li>• <code>mimeTypeMessage</code></li><li>• <code>sizeNotDetectedMessage</code></li><li>• <code>maxWidthMessage</code></li><li>• <code>minWidthMessage</code></li><li>• <code>maxHeightMessage</code></li><li>• <code>minHeightMessage</code></li><li>• <code>maxRatioMessage</code></li><li>• <code>minRatioMessage</code></li><li>• <code>allowSquareMessage</code></li><li>• <code>allowLandscapeMessage</code></li><li>• <code>allowPortraitMessage</code></li><li>• <code>corruptedMessage</code></li><li>• See <code>File</code> for inherited options</li></ul>

Class	<i>Image</i> <sup>1</sup>
Validator	<i>ImageValidator</i> <sup>2</sup>

## Basic Usage

This constraint is most commonly used on a property that will be rendered in a form as a *FileType* field. For example, suppose you're creating an author form where you can upload a "headshot" image for the author. In your form, the `headshot` property would be a `file` type. The `Author` class might look as follows:

```
Listing 80-1 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\HttpFoundation\File\File;
5
6 class Author
7 {
8     protected $headshot;
9
10    public function setHeadshot(File $file = null)
11    {
12        $this->headshot = $file;
13    }
14
15    public function getHeadshot()
16    {
17        return $this->headshot;
18    }
19 }
```

To guarantee that the `headshot` `File` object is a valid image and that it is between a certain size, add the following:

```
Listing 80-2 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Image(
10     *     minWidth = 200,
11     *     maxWidth = 400,
12     *     minHeight = 200,
13     *     maxHeight = 400
14     * )
15     */
16    protected $headshot;
17 }
```

The `headshot` property is validated to guarantee that it is a real image and that it is between a certain width and height.

You may also want to guarantee the `headshot` image to be square. In this case you can disable portrait and landscape orientations as shown in the following code:

```
Listing 80-3 1 // src/Entity/Author.php
2 namespace App\Entity;
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Image.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/ImageValidator.html>

```

3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Image(
10     *     allowLandscape = false,
11     *     allowPortrait = false
12     * )
13     */
14     protected $headshot;
15 }

```

You can mix all the constraint options to create powerful validation rules.

## Options

This constraint shares all of its options with the *File* constraint. It does, however, modify two of the default option values and add several other options.

### mimeTypes

**type:** array or string **default:** image/\*

You can find a list of existing image mime types on the *IANA website*<sup>3</sup>.

### mimeTypesMessage

**type:** string **default:** This file is not a valid image.

### minWidth

**type:** integer

If set, the width of the image file must be greater than or equal to this value in pixels.

### maxWidth

**type:** integer

If set, the width of the image file must be less than or equal to this value in pixels.

### minHeight

**type:** integer

If set, the height of the image file must be greater than or equal to this value in pixels.

### maxHeight

**type:** integer

If set, the height of the image file must be less than or equal to this value in pixels.

---

3. <http://www.iana.org/assignments/media-types/image/index.html>

## minPixels

**type:** integer

If set, the amount of pixels of the image file must be greater than or equal to this value.

## maxPixels

**type:** integer

If set, the amount of pixels of the image file must be less than or equal to this value.

## maxRatio

**type:** float

If set, the aspect ratio (**width / height**) of the image file must be less than or equal to this value.

## minRatio

**type:** float

If set, the aspect ratio (**width / height**) of the image file must be greater than or equal to this value.

## allowSquare

**type:** Boolean **default:** true

If this option is false, the image cannot be a square. If you want to force a square image, then set leave this option as its default **true** value and set `allowLandscape` and `allowPortrait` both to **false**.

## allowLandscape

**type:** Boolean **default:** true

If this option is false, the image cannot be landscape oriented.

## allowPortrait

**type:** Boolean **default:** true

If this option is false, the image cannot be portrait oriented.

## detectCorrupted

**type:** boolean **default:** false

If this option is true, the image contents are validated to ensure that the image is not corrupted. This validation is done with PHP's `imagecreatefromstring`<sup>4</sup> function, which requires the *PHP GD extension*<sup>5</sup> to be enabled.

## sizeNotDetectedMessage

**type:** string **default:** The size of the image could not be detected.

---

4. <https://secure.php.net/manual/en/function.imagecreatefromstring.php>

5. <http://php.net/manual/en/book.image.php>

If the system is unable to determine the size of the image, this error will be displayed. This will only occur when at least one of the size constraint options has been set.

#### maxWidthMessage

**type:** string **default:** The image width is too big ({{ width }}px). Allowed maximum width is {{ max\_width }}px.

The error message if the width of the image exceeds maxWidth.

#### minWidthMessage

**type:** string **default:** The image width is too small ({{ width }}px). Minimum width expected is {{ min\_width }}px.

The error message if the width of the image is less than minWidth.

#### maxHeightMessage

**type:** string **default:** The image height is too big ({{ height }}px). Allowed maximum height is {{ max\_height }}px.

The error message if the height of the image exceeds maxHeight.

#### minHeightMessage

**type:** string **default:** The image height is too small ({{ height }}px). Minimum height expected is {{ min\_height }}px.

The error message if the height of the image is less than minHeight.

#### maxPixelsMessage

**type:** string **default:** The image has too many pixels ({{ pixels }} pixels). Maximum amount expected is {{ max\_pixels }} pixels.

The error message if the amount of pixels of the image exceeds maxPixels.

#### minPixelsMessage

**type:** string **default:** The image has too few pixels ({{ pixels }} pixels). Minimum amount expected is {{ min\_pixels }} pixels.

The error message if the amount of pixels of the image is less than minPixels.

#### maxRatioMessage

**type:** string **default:** The image ratio is too big ({{ ratio }}). Allowed maximum ratio is {{ max\_ratio }}

The error message if the aspect ratio of the image exceeds maxRatio.

#### minRatioMessage

**type:** string **default:** The image ratio is too small ({{ ratio }}). Minimum ratio expected is {{ min\_ratio }}

The error message if the aspect ratio of the image is less than minRatio.

#### allowSquareMessage

**type:** string **default:** The image is square ({{ width }}x{{ height }}px). Square images are not allowed

The error message if the image is square and you set allowSquare to **false**.

#### allowLandscapeMessage

**type:** string **default:** The image is landscape oriented ({{ width }}x{{ height }}px). Landscape oriented images are not allowed

The error message if the image is landscape oriented and you set allowLandscape to **false**.

#### allowPortraitMessage

**type:** string **default:** The image is portrait oriented ({{ width }}x{{ height }}px). Portrait oriented images are not allowed

The error message if the image is portrait oriented and you set allowPortrait to **false**.

#### corruptedMessage

**type:** string **default:** The image file is corrupted.

The error message when the detectCorrupted option is enabled and the image is corrupted.

## Chapter 81

# CardScheme

This constraint ensures that a credit card number is valid for a given credit card company. It can be used to validate the number before trying to initiate a payment through a payment gateway.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• schemes</li><li>• message</li><li>• payload</li></ul>
Class	<i>CardScheme</i> <sup>1</sup>
Validator	<i>CardSchemeValidator</i> <sup>2</sup>

## Basic Usage

To use the **CardScheme** validator, simply apply it to a property or method on an object that will contain a credit card number.

```
Listing 81-1 1 // src/Entity/Transaction.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Transaction
7 {
8     /**
9      * @Assert\CardScheme(
10     *     schemes={"VISA"},
11     *     message="Your credit card number is invalid."
12     * )
13     */
14     protected $cardNumber;
15 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CardScheme.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CardSchemeValidator.html>

# Available Options

## schemes

**type:** `mixed` [default option]

This option is required and represents the name of the number scheme used to validate the credit card number, it can either be a string or an array. Valid values are:

- AMEX
- CHINA\_UNIONPAY
- DINERS
- DISCOVER
- INSTAPAYMENT
- JCB
- LASER
- MAESTRO
- MASTERCARD
- VISA

For more information about the used schemes, see *Wikipedia: Issuer identification number (IIN)*<sup>3</sup>.

## message

**type:** `string` **default:** `Unsupported card type or invalid card number.`

The message shown when the value does not pass the `CardScheme` check.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

3. [https://en.wikipedia.org/wiki/Bank\\_card\\_number#Issuer\\_identification\\_number\\_.28IIN.29](https://en.wikipedia.org/wiki/Bank_card_number#Issuer_identification_number_.28IIN.29)

## Chapter 82

# Currency

Validates that a value is a valid *3-letter ISO 4217*<sup>1</sup> currency name.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Currency</i> <sup>2</sup>
Validator	<i>CurrencyValidator</i> <sup>3</sup>

## Basic Usage

If you want to ensure that the **currency** property of an **Order** is a valid currency, you could do the following:

Listing 82-1

```
1 // src/Entity/Order.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Order
7 {
8     /**
9      * @Assert\Currency
10     */
11     protected $currency;
12 }
```

---

1. [https://en.wikipedia.org/wiki/ISO\\_4217](https://en.wikipedia.org/wiki/ISO_4217)

2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Currency.html>

3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CurrencyValidator.html>

# Options

## message

**type:** string **default:** This value is not a valid currency.

This is the message that will be shown if the value is not a valid currency.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 83

# Luhn

This constraint is used to ensure that a credit card number passes the *Luhn algorithm*<sup>1</sup>. It is useful as a first step to validating a credit card: before communicating with a payment gateway.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Luhn</i> <sup>2</sup>
Validator	<i>LuhnValidator</i> <sup>3</sup>

## Basic Usage

To use the Luhn validator, simply apply it to a property on an object that will contain a credit card number.

```
Listing 83-1 1 // src/Entity/Transaction.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Transaction
7 {
8     /**
9      * @Assert\Luhn(message="Please check your credit card number.")
10     */
11     protected $cardNumber;
12 }
```

---

1. [https://en.wikipedia.org/wiki/Luhn\\_algorithm](https://en.wikipedia.org/wiki/Luhn_algorithm)  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Luhn.html>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/LuhnValidator.html>

## Available Options

### message

**type:** string **default:** Invalid card number.

The default message supplied when the value does not pass the Luhn check.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 84

# Iban

This constraint is used to ensure that a bank account number has the proper format of an *International Bank Account Number (IBAN)*<sup>1</sup>. IBAN is an internationally agreed means of identifying bank accounts across national borders with a reduced risk of propagating transcription errors.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Iban</i> <sup>2</sup>
Validator	<i>IbanValidator</i> <sup>3</sup>

## Basic Usage

To use the Iban validator, simply apply it to a property on an object that will contain an International Bank Account Number.

```
Listing 84-1 1 // src/Entity/Transaction.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Transaction
7 {
8     /**
9      * @Assert\Iban(
10     *     message="This is not a valid International Bank Account Number (IBAN). "
11     * )
12     */
13     protected $bankAccountNumber;
14 }
```

- 
1. [https://en.wikipedia.org/wiki/International\\_Bank\\_Account\\_Number](https://en.wikipedia.org/wiki/International_Bank_Account_Number)
  2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Iban.html>
  3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IbanValidator.html>

## Available Options

### message

**type:** string **default:** This is not a valid International Bank Account Number (IBAN).

The default message supplied when the value does not pass the Iban check.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 85

# Bic

This constraint is used to ensure that a value has the proper format of a *Business Identifier Code (BIC)*<sup>1</sup>. BIC is an internationally agreed means to uniquely identify both financial and non-financial institutions.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<i>Bic</i> <sup>2</sup>
Validator	<i>BicValidator</i> <sup>3</sup>

## Basic Usage

To use the Bic validator, simply apply it to a property on an object that will contain a Business Identifier Code (BIC).

```
Listing 85-1 1 // src/Entity/Transaction.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Transaction
7 {
8     /**
9      * @Assert\Bic()
10     */
11     protected $businessIdentifierCode;
12 }
```

---

1. [https://en.wikipedia.org/wiki/Business\\_Identifier\\_Code](https://en.wikipedia.org/wiki/Business_Identifier_Code)  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Bic.html>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/BicValidator.html>

## Available Options

### message

**type:** string **default:** This is not a valid Business Identifier Code (BIC).

The default message supplied when the value does not pass the BIC check.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 86

# Isbn

This constraint validates that an *International Standard Book Number (ISBN)*<sup>1</sup> is either a valid ISBN-10 or a valid ISBN-13.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• type</li><li>• message</li><li>• isbn10Message</li><li>• isbn13Message</li><li>• bothIsbnMessage</li><li>• payload</li></ul>
Class	<i>Isbn</i> <sup>2</sup>
Validator	<i>IsbnValidator</i> <sup>3</sup>

## Basic Usage

To use the **Isbn** validator, simply apply it to a property or method on an object that will contain an ISBN.

Listing 86-1

```
1 // src/Entity/Book.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Book
7 {
8     /**
9      * @Assert\Isbn(
10      *     type = "isbn10",
```

---

1. <https://en.wikipedia.org/wiki/Isbn>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Isbn.html>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IsbnValidator.html>

```
11     *   message = "This value is not valid."
12     * )
13     */
14     protected $isbn;
15 }
```

## Available Options

### type

**type:** string **default:** null

The type of ISBN to validate against. Valid values are `isbn10`, `isbn13` and `null` to accept any kind of ISBN.

### message

**type:** string **default:** null

The message that will be shown if the value is not valid. If not `null`, this message has priority over all the other messages.

### isbn10Message

**type:** string **default:** This value is not a valid ISBN-10.

The message that will be shown if the type option is `isbn10` and the given value does not pass the ISBN-10 check.

### isbn13Message

**type:** string **default:** This value is not a valid ISBN-13.

The message that will be shown if the type option is `isbn13` and the given value does not pass the ISBN-13 check.

### bothIsbnMessage

**type:** string **default:** This value is neither a valid ISBN-10 nor a valid ISBN-13.

The message that will be shown if the type option is `null` and the given value does not pass any of the ISBN checks.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 87

# Issn

Validates that a value is a valid *International Standard Serial Number (ISSN)*<sup>1</sup>.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• caseSensitive</li><li>• requireHyphen</li><li>• payload</li></ul>
Class	<i>Issn</i> <sup>2</sup>
Validator	<i>IssnValidator</i> <sup>3</sup>

## Basic Usage

Listing 87-1

```
1 // src/Entity/Journal.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Journal
7 {
8     /**
9      * @Assert\Issn
10     */
11     protected $issn;
12 }
```

---

1. <https://en.wikipedia.org/wiki/Issn>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Issn.html>  
3. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/IssnValidator.html>

# Options

## message

**type:** String default: This value is not a valid ISSN.

The message shown if the given value is not a valid ISSN.

## caseSensitive

**type:** boolean default: false

The validator will allow ISSN values to end with a lower case 'x' by default. When switching this to **true**, the validator requires an upper case 'X'.

## requireHyphen

**type:** boolean default: false

The validator will allow non hyphenated ISSN values by default. When switching this to **true**, the validator requires a hyphenated ISSN value.

## payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 88

# Callback

The purpose of the Callback constraint is to create completely custom validation rules and to assign any validation errors to specific fields on your object. If you're using validation with forms, this means that you can make these custom errors display next to a specific field, instead of simply at the top of your form.

This process works by specifying one or more *callback* methods, each of which will be called during the validation process. Each of those methods can do anything, including creating and assigning validation errors.

A callback method itself doesn't *fail* or return any value. Instead, as you'll see in the example, a callback method has the ability to directly add validator "violations".

Applies to	class
Options	<ul style="list-style-type: none"><li>• callback</li><li>• payload</li></ul>
Class	<i>Callback</i> <sup>1</sup>
Validator	<i>CallbackValidator</i> <sup>2</sup>

## Configuration

Listing 88-1

```
1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5 use Symfony\Component\Validator\Context\ExecutionContextInterface;
6
```

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Callback.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/CallbackValidator.html>

```

7 class Author
8 {
9     /**
10     * @Assert\Callback
11     */
12     public function validate(ExecutionContextInterface $context, $payload)
13     {
14         // ...
15     }
16 }

```

## The Callback Method

The callback method is passed a special `ExecutionContextInterface` object. You can set "violations" directly on this object and determine to which field those errors should be attributed:

Listing 88-2

```

1 // ...
2 use Symfony\Component\Validator\Context\ExecutionContextInterface;
3
4 class Author
5 {
6     // ...
7     private $firstName;
8
9     public function validate(ExecutionContextInterface $context, $payload)
10    {
11        // somehow you have an array of "fake names"
12        $fakeNames = array(/* ... */);
13
14        // check if the name is actually a fake name
15        if (in_array($this->getFirstName(), $fakeNames)) {
16            $context->buildViolation('This name sounds totally fake!')
17                ->atPath('firstName')
18                ->addViolation();
19        }
20    }
21 }

```

## Static Callbacks

You can also use the constraint with static methods. Since static methods don't have access to the object instance, they receive the object as the first argument:

Listing 88-3

```

1 public static function validate($object, ExecutionContextInterface $context, $payload)
2 {
3     // somehow you have an array of "fake names"
4     $fakeNames = array(/* ... */);
5
6     // check if the name is actually a fake name
7     if (in_array($object->getFirstName(), $fakeNames)) {
8         $context->buildViolation('This name sounds totally fake!')
9             ->atPath('firstName')
10            ->addViolation();
11     };
12 }
13 }

```

## External Callbacks and Closures

If you want to execute a static callback method that is not located in the class of the validated object, you can configure the constraint to invoke an array callable as supported by PHP's `call_user_func`<sup>3</sup> function. Suppose your validation function is `Acme\Validator::validate()`:

```
Listing 88-4 1 namespace Acme;
2
3 use Symfony\Component\Validator\Context\ExecutionContextInterface;
4
5 class Validator
6 {
7     public static function validate($object, ExecutionContextInterface $context, $payload)
8     {
9         // ...
10    }
11 }
```

You can then use the following configuration to invoke this validator:

```
Listing 88-5 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 /**
7  * @Assert\Callback({"Acme\Validator", "validate"})
8  */
9 class Author
10 {
11 }
```

The Callback constraint does *not* support global callback functions nor is it possible to specify a global function or a service method as callback. To validate using a service, you should *create a custom validation constraint* and add that new constraint to your class.

When configuring the constraint via PHP, you can also pass a closure to the constructor of the Callback constraint:

```
Listing 88-6 1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Context\ExecutionContextInterface;
5
6 use Symfony\Component\Validator\Mapping\ClassMetadata;
7 use Symfony\Component\Validator\Constraints as Assert;
8
9 class Author
10 {
11     public static function loadValidatorMetadata(ClassMetadata $metadata)
12     {
13         $callback = function ($object, ExecutionContextInterface $context, $payload) {
14             // ...
15         };
16
17         $metadata->addConstraint(new Assert\Callback($callback));
18     }
19 }
```

---

3. <https://secure.php.net/manual/en/function.call-user-func.php>

# Options

## callback

**type:** `string`, `array` or `Closure` [default option]

The callback option accepts three different formats for specifying the callback method:

- A **string** containing the name of a concrete or static method;
- An array callable with the format `array('<Class>', '<method>')`;
- A closure.

Concrete callbacks receive an *ExecutionContextInterface*<sup>4</sup> instance as only argument.

Static or closure callbacks receive the validated object as the first argument and the *ExecutionContextInterface*<sup>5</sup> instance as the second argument.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

---

4. <https://api.symfony.com/4.0/Symfony/Component/Validator/Context/ExecutionContextInterface.html>

5. <https://api.symfony.com/4.0/Symfony/Component/Validator/ExecutionContextInterface.html>

## Chapter 89

# Expression

This constraint allows you to use an expression for more complex, dynamic validation. See *Basic Usage* for an example. See *Callback* for a different constraint that gives you similar flexibility.

Applies to	class or property/method
Options	<ul style="list-style-type: none"><li>• expression</li><li>• message</li><li>• payload</li></ul>
Class	<i>Expression</i> <sup>1</sup>
Validator	<i>ExpressionValidator</i> <sup>2</sup>

## Basic Usage

Imagine you have a class `BlogPost` with `category` and `isTechnicalPost` properties:

```
Listing 89-1 1 // src/Model/BlogPost.php
2 namespace App\Model;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class BlogPost
7 {
8     private $category;
9
10    private $isTechnicalPost;
11
12    // ...
13
14    public function getCategory()
15    {
16        return $this->category;
17    }
18 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Expression.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/ExpressionValidator.html>

```

17     }
18
19     public function setIsTechnicalPost($isTechnicalPost)
20     {
21         $this->isTechnicalPost = $isTechnicalPost;
22     }
23
24     // ...
25 }

```

To validate the object, you have some special requirements:

1. If `isTechnicalPost` is true, then `category` must be either `php` or `symfony`;
2. If `isTechnicalPost` is false, then `category` can be anything.

One way to accomplish this is with the Expression constraint:

Listing 89-2

```

1 // src/Model/BlogPost.php
2 namespace App\Model;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 /**
7  * @Assert\Expression(
8  *     "this.getCategory() in ['php', 'symfony'] or !this.isTechnicalPost()",
9  *     message="If this is a tech post, the category should be either php or symfony!"
10  * )
11  */
12 class BlogPost
13 {
14     // ...
15 }

```

The expression option is the expression that must return true in order for validation to pass. To learn more about the expression language syntax, see *The Expression Syntax*.

## Mapping the Error to a Specific Field

You can also attach the constraint to a specific property and still validate based on the values of the entire entity. This is handy if you want to attach the error to a specific field. In this context, **value** represents the value of `isTechnicalPost`.

Listing 89-3

```

1 // src/Model/BlogPost.php
2 namespace App\Model;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class BlogPost
7 {
8     // ...
9
10    /**
11     * @Assert\Expression(
12     *     "this.getCategory() in ['php', 'symfony'] or value == false",
13     *     message="If this is a tech post, the category should be either php or symfony!"
14     * )
15     */
16    private $isTechnicalPost;
17
18    // ...
19 }

```

For more information about the expression and what variables are available to you, see the expression option details below.

# Available Options

## expression

**type:** `string` [default option]

The expression that will be evaluated. If the expression evaluates to a false value (using `==`, not `===`), validation will fail.

To learn more about the expression language syntax, see *The Expression Syntax*.

Inside of the expression, you have access to up to 2 variables:

Depending on how you use the constraint, you have access to 1 or 2 variables in your expression:

- `this`: The object being validated (e.g. an instance of `BlogPost`);
- `value`: The value of the property being validated (only available when the constraint is applied directly to a property);

## message

**type:** `string` **default:** `This value is not valid.`

The default message supplied when the expression evaluates to false.

## payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 90

# All

When applied to an array (or Traversable object), this constraint allows you to apply a collection of constraints to each element of the array.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• constraints</li><li>• payload</li></ul>
Class	<i>All</i> <sup>1</sup>
Validator	<i>AllValidator</i> <sup>2</sup>

## Basic Usage

Suppose that you have an array of strings and you want to validate each entry in that array:

```
Listing 90-1 1 // src/Entity/User.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class User
7 {
8     /**
9      * @Assert\All({
10      *     @Assert\NotBlank,
11      *     @Assert\Length(min=5)
12      * })
13     */
14     protected $favoriteColors = array();
15 }
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/All.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/AllValidator.html>

Now, each entry in the `favoriteColors` array will be validated to not be blank and to be at least 5 characters long.

## Options

### constraints

**type:** `array` [default option]

This required option is the array of validation constraints that you want to apply to each element of the underlying array.

### payload

**type:** `mixed` **default:** `null`

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 91

# UserPassword

This validates that an input value is equal to the current authenticated user's password. This is useful in a form where a user can change their password, but needs to enter their old password for security.

This should **not** be used to validate a login form, since this is done automatically by the security system.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• message</li><li>• payload</li></ul>
Class	<code>UserPassword<sup>1</sup></code>
Validator	<code>UserPasswordValidator<sup>2</sup></code>

## Basic Usage

Suppose you have a `ChangePassword` class, that's used in a form where the user can change their password by entering their old password and a new password. This constraint will validate that the old password matches the user's current password:

```
Listing 91-1 1 // src/Form/Model/ChangePassword.php
2 namespace App\Form\Model;
3
4 use Symfony\Component\Security\Core\Validator\Constraints as SecurityAssert;
5
6 class ChangePassword
7 {
8     /**
9      * @SecurityAssert\UserPassword(
```

1. <https://api.symfony.com/4.0/Symfony/Component/Security/Core/Validator/Constraints/UserPassword.html>  
2. <https://api.symfony.com/4.0/Symfony/Component/Security/Core/Validator/Constraints/UserPasswordValidator.html>

```
10     *   message = "Wrong value for your current password"
11     * )
12     */
13     protected $oldPassword;
14 }
```

## Options

### message

**type:** message **default:** This value should be the user current password.

This is the message that's displayed when the underlying string does *not* match the current user's password.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 92

# Valid

This constraint is used to enable validation on objects that are embedded as properties on an object being validated. This allows you to validate an object and all sub-objects associated with it.

Applies to	property or method
Options	<ul style="list-style-type: none"><li>• <code>traverse</code></li><li>• <code>payload</code></li></ul>
Class	<code>Valid<sup>1</sup></code>

By default the `error_bubbling` option is enabled for the *collection Field Type*, which passes the errors to the parent form. If you want to attach the errors to the locations where they actually occur you have to set `error_bubbling` to `false`.

## Basic Usage

In the following example, create two classes `Author` and `Address` that both have constraints on their properties. Furthermore, `Author` stores an `Address` instance in the `$address` property:

```
Listing 92-1 1 // src/Entity/Address.php
2 namespace App\Entity;
3
4 class Address
5 {
6     protected $street;
7     protected $zipCode;
8 }
```

```
Listing 92-2 1 // src/Entity/Author.php
2 namespace App\Entity;
```

---

1. <https://api.symfony.com/4.0/Symfony/Component/Validator/Constraints/Valid.html>

```

3
4 class Author
5 {
6     protected $firstName;
7     protected $lastName;
8     protected $address;
9 }

```

Listing 92-3

```

1 // src/Entity/Address.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Address
7 {
8     /**
9      * @Assert\NotBlank()
10     */
11     protected $street;
12
13     /**
14      * @Assert\NotBlank
15      * @Assert\Length(max=5)
16     */
17     protected $zipCode;
18 }
19
20 // src/Entity/Author.php
21 namespace App\Entity;
22
23 use Symfony\Component\Validator\Constraints as Assert;
24
25 class Author
26 {
27     /**
28      * @Assert\NotBlank
29      * @Assert\Length(min=4)
30     */
31     protected $firstName;
32
33     /**
34      * @Assert\NotBlank
35     */
36     protected $lastName;
37
38     protected $address;
39 }

```

With this mapping, it is possible to successfully validate an author with an invalid address. To prevent that, add the **Valid** constraint to the **\$address** property.

Listing 92-4

```

1 // src/Entity/Author.php
2 namespace App\Entity;
3
4 use Symfony\Component\Validator\Constraints as Assert;
5
6 class Author
7 {
8     /**
9      * @Assert\Valid
10     */
11     protected $address;
12 }

```

If you validate an author with an invalid address now, you can see that the validation of the **Address** fields failed.

Listing 92-5

- 1 App\Entity\Author.address.zipCode:
- 2 This value is too long. It should have 5 characters or less.

## Options

### traverse

**type:** boolean **default:** true

If this constraint is applied to a property that holds an array of objects, then each object in that array will be validated only if this option is set to **true**.

### payload

**type:** mixed **default:** null

This option can be used to attach arbitrary domain-specific data to a constraint. The configured payload is not used by the Validator component, but its processing is completely up to you.

For example, you may want to use *several error levels* to present failed constraints differently in the front-end depending on the severity of the error.

## Chapter 93

# Twig Template Form Function and Variable Reference

When working with forms in a template, there are two powerful things at your disposal:

- Functions for rendering each part of a form;
- Variables for getting *any* information about any field.

You'll use functions often to render your fields. Variables, on the other hand, are less commonly-used, but infinitely powerful since you can access a fields label, id attribute, errors and anything else about the field.

## Form Rendering Functions

This reference manual covers all the possible Twig functions available for rendering forms. There are several different functions available and each is responsible for rendering a different part of a form (e.g. labels, errors, widgets, etc).

### form(view, variables)

Renders the HTML of a complete form.

```
Listing 93-1 1 {# render the form and change the submission method #}  
2 {{ form(form, {'method': 'GET'}) }}
```

You will mostly use this helper for prototyping or if you use custom form themes. If you need more flexibility in rendering the form, you should use the other helpers to render individual parts of the form instead:

```
Listing 93-2 1 {{ form_start(form) }}  
2     {{ form_errors(form) }}  
3
```

```

4     {{ form_row(form.name) }}
5     {{ form_row(form.dueDate) }}
6
7     {{ form_row(form.submit, { 'label': 'Submit me' }) }}
8 {{ form_end(form) }}

```

## form\_start(view, variables)

Renders the start tag of a form. This helper takes care of printing the configured method and target action of the form. It will also include the correct `enctype` property if the form contains upload fields.

Listing 93-3

```

1 {# render the start tag and change the submission method #}
2 {{ form_start(form, {'method': 'GET'}) }}

```

## form\_end(view, variables)

Renders the end tag of a form.

Listing 93-4

```

1 {{ form_end(form) }}

```

This helper also outputs `form_rest()` unless you set `render_rest` to false:

Listing 93-5

```

1 {# don't render unrendered fields #}
2 {{ form_end(form, {'render_rest': false}) }}

```

## form\_label(view, label, variables)

Renders the label for the given field. You can optionally pass the specific label you want to display as the second argument.

Listing 93-6

```

1 {{ form_label(form.name) }}
2
3 {# The two following syntaxes are equivalent #}
4 {{ form_label(form.name, 'Your Name', {'label_attr': {'class': 'foo'}}) }}
5
6 {{ form_label(form.name, null, {
7     'label': 'Your name',
8     'label_attr': {'class': 'foo'}
9 }) }}

```

See "More about Form Variables" to learn about the `variables` argument.

## form\_errors(view)

Renders any errors for the given field.

Listing 93-7

```

1 {{ form_errors(form.name) }}
2
3 {# render any "global" errors #}
4 {{ form_errors(form) }}

```

## form\_widget(view, variables)

Renders the HTML widget of a given field. If you apply this to an entire form or collection of fields, each underlying form row will be rendered.

```
Listing 93-8 1 {# render a widget, but add a "foo" class to it #}  
2 {{ form_widget(form.name, {'attr': {'class': 'foo'}}) }}
```

The second argument to `form_widget()` is an array of variables. The most common variable is `attr`, which is an array of HTML attributes to apply to the HTML widget. In some cases, certain types also have other template-related options that can be passed. These are discussed on a type-by-type basis. The `attributes` are not applied recursively to child fields if you're rendering many fields at once (e.g. `form_widget(form)`).

See "More about Form Variables" to learn more about the `variables` argument.

## form\_row(view, variables)

Renders the "row" of a given field, which is the combination of the field's label, errors and widget.

```
Listing 93-9 1 {# render a field row, but display a label with text "foo" #}  
2 {{ form_row(form.name, {'label': 'foo'}) }}
```

The second argument to `form_row()` is an array of variables. The templates provided in Symfony only allow to override the label as shown in the example above.

See "More about Form Variables" to learn about the `variables` argument.

## form\_rest(view, variables)

This renders all fields that have not yet been rendered for the given form. It's a good idea to always have this somewhere inside your form as it'll render hidden fields for you and make any fields you forgot to render more obvious (since it'll render the field for you).

```
Listing 93-10 1 {{ form_rest(form) }}
```

## Form Tests Reference

Tests can be executed by using the `is` operator in Twig to create a condition. Read *the Twig documentation*<sup>1</sup> for more information.

### selectedchoice(selected\_value)

This test will check if the current choice is equal to the `selected_value` or if the current choice is in the array (when `selected_value` is an array).

```
Listing 93-11 1 <option {% if choice is selectedchoice(value) %} selected="selected" {% endif %} ...>
```

---

1. <http://twig.sensiolabs.org/doc/templates.html#test-operator>

## More about Form Variables

For a full list of variables, see: [Form Variables Reference](#).

In almost every Twig function above, the final argument is an array of "variables" that are used when rendering that one part of the form. For example, the following would render the "widget" for a field and modify its attributes to include a special class:

```
Listing 93-12 1  {# render a widget, but add a "foo" class to it #}
                2  {{ form_widget(form.name, { 'attr': {'class': 'foo'} }) }}
```

The purpose of these variables - what they do & where they come from - may not be immediately clear, but they're incredibly powerful. Whenever you render any part of a form, the block that renders it makes use of a number of variables. By default, these blocks live inside *form\_div\_layout.html.twig*<sup>2</sup>.

Look at the `form_label` as an example:

```
Listing 93-13 1  {% block form_label %}
                2  {% if not compound %}
                3      {% set label_attr = label_attr|merge({'for': id}) %}
                4  {% endif %}
                5
                6  {% if required %}
                7      {% set label_attr = label_attr|merge({
                8          'class': (label_attr.class|default('') ~ ' required')|trim
                9      }) %}
                10 {% endif %}
                11
                12 {% if label is empty %}
                13     {% set label = name|humanize %}
                14 {% endif %}
                15
                16 <label
                17     {% for attrname, attrvalue in label_attr -%}
                18         {{ attrname }}="{{ attrvalue }}"
                19     {%- endfor %}
                20 >
                21     {{ label|trans({}, translation_domain) }}
                22 </label>
                23 {% endblock form_label %}
```

This block makes use of several variables: `compound`, `label_attr`, `required`, `label`, `name` and `translation_domain`. These variables are made available by the form rendering system. But more importantly, these are the variables that you can override when calling `form_label()` (since in this example, you're rendering the label).

The exact variables available to override depends on which part of the form you're rendering (e.g. label versus widget) and which field you're rendering (e.g. a **choice** widget has an extra **expanded** option). If you get comfortable with looking through *form\_div\_layout.html.twig*<sup>3</sup>, you'll always be able to see what options you have available.

Behind the scenes, these variables are made available to the `FormView` object of your form when the Form component calls `buildView()` and `finishView()` on each "node" of your form tree. To see what "view" variables a particular field has, find the source code for the form field (and its parent fields) and look at the above two functions.

2. [https://github.com/symfony/symfony/blob/master/src/Symfony/Bridge/Twig/Resources/views/Form/form\\_div\\_layout.html.twig](https://github.com/symfony/symfony/blob/master/src/Symfony/Bridge/Twig/Resources/views/Form/form_div_layout.html.twig)

3. [https://github.com/symfony/symfony/blob/master/src/Symfony/Bridge/Twig/Resources/views/Form/form\\_div\\_layout.html.twig](https://github.com/symfony/symfony/blob/master/src/Symfony/Bridge/Twig/Resources/views/Form/form_div_layout.html.twig)

If you're rendering an entire form at once (or an entire embedded form), the **variables** argument will only be applied to the form itself and not its children. In other words, the following will **not** pass a "foo" class attribute to all of the child fields in the form:

```
Listing 93-14 1  {# does **not** work - the variables are not recursive #}
                2  {{ form_widget(form, { 'attr': {'class': 'foo'} }) }}
```

## Form Variables Reference

The following variables are common to every field type. Certain field types may have even more variables and some variables here only really apply to certain types.

Assuming you have a **form** variable in your template and you want to reference the variables on the **name** field, accessing the variables is done by using a public **vars** property on the *FormView*<sup>4</sup> object:

```
Listing 93-15 1  <label for="{{ form.name.vars.id }}"
                2  class="{{ form.name.vars.required ? 'required' : '' }}">
                3  {{ form.name.vars.label }}
                4  </label>
```

Variable	Usage
form	The current <i>FormView</i> instance.
id	The <code>id</code> HTML attribute to be rendered.
name	The name of the field (e.g. <code>title</code> ) - but not the <code>name</code> HTML attribute, which is <code>full_name</code> .
full_name	The name HTML attribute to be rendered.
errors	An array of any errors attached to <i>this</i> specific field (e.g. <code>form.title.errors</code> ). Note that you can't use <code>form.errors</code> to determine if a form is valid, since this only returns "global" errors: some individual fields may have errors. Instead, use the <code>valid</code> option.
submitted	Returns <code>true</code> or <code>false</code> depending on whether the whole form is submitted
valid	Returns <code>true</code> or <code>false</code> depending on whether the whole form is valid.
value	The value that will be used when rendering (commonly the <code>value</code> HTML attribute).
disabled	If <code>true</code> , <code>disabled="disabled"</code> is added to the field.
required	If <code>true</code> , a <code>required</code> attribute is added to the field to activate HTML5 validation. Additionally, a <code>required</code> class is added to the label.
label	The string label that will be rendered.
multipart	If <code>true</code> , <code>form_enctype</code> will render <code>enctype="multipart/form-data"</code> . This only applies to the root form element.
attr	A key-value array that will be rendered as HTML attributes on the field.
label_attr	A key-value array that will be rendered as HTML attributes on the label.
compound	Whether or not a field is actually a holder for a group of children fields (for example, a <code>choice</code> field, which is actually a group of checkboxes).

4. <https://api.symfony.com/4.0/Symfony/Component/Form/FormView.html>

<b>Variable</b>	<b>Usage</b>
block_prefixes	An array of all the names of the parent types.
translation_domain	The domain of the translations for this form.
cache_key	A unique key which is used for caching.
data	The normalized data of the type.
method	The method of the current form (POST, GET, etc.).
action	The action of the current form.

## Chapter 94

# Symfony Twig Extensions

Twig is the default template engine for Symfony. By itself, it already contains a lot of built-in functions, filters, tags and tests. You can learn more about them from the *Twig Reference*<sup>1</sup>.

The Symfony framework adds quite a few extra functions, filters, tags and tests to seamlessly integrate the various Symfony components with Twig templates. The following sections describe these extra features.

Technically, most of the extensions live in the *Twig Bridge*<sup>2</sup>. That code might give you some ideas when you need to write your own Twig extension as described in *How to Write a custom Twig Extension*.

This reference only covers the Twig extensions provided by the Symfony framework. You are probably using some other bundles as well, and those might come with their own extensions not covered here.

The *Twig Extensions repository*<sup>3</sup> contains some additional Twig extensions that do not belong to the Twig core, so you might want to have a look at the *Twig Extensions documentation*<sup>4</sup>.

## Functions

### render

Listing 94-1 1 `{{ render(uri, options = []) }}`

**uri**

**type:** string | ControllerReference

---

1. <http://twig.sensiolabs.org/documentation#reference>  
2. <https://github.com/symfony/symfony/tree/master/src/Symfony/Bridge/Twig/Extension>  
3. <https://github.com/twigphp/Twig-extensions>  
4. <http://twig-extensions.readthedocs.io/en/latest/>

**options** (*optional*)

**type:** array **default:** []

Renders the fragment for the given controller (using the controller function) or URI. For more information, see *How to Embed Controllers in a Template*.

The render strategy can be specified in the **strategy** key of the options.

The URI can be generated by other functions, like path and url.

## render\_esi

Listing 94-2 1 {{ render\_esi(uri, options = []) }}

**uri**

**type:** string | ControllerReference

**options** (*optional*)

**type:** array **default:** []

Generates an ESI tag when possible or falls back to the behavior of render function instead. For more information, see *How to Embed Controllers in a Template*.

The URI can be generated by other functions, like path and url.

The **render\_esi()** function is an example of the shortcut functions of **render**. It automatically sets the strategy based on what's given in the function name, e.g. **render\_hinclude()** will use the `hinclude.js` strategy. This works for all **render\_\***() functions.

## controller

Listing 94-3 1 {{ controller(controller, attributes = [], query = []) }}

**controller**

**type:** string

**attributes** (*optional*)

**type:** array **default:** []

**query** (*optional*)

**type:** array **default:** []

Returns an instance of **ControllerReference** to be used with functions like `render()` and `render_esi()`.

## asset

Listing 94-4 1 {{ asset(path, packageName = null) }}

**path**  
**type:** string

**packageName** (*optional*)  
**type:** string | null **default:** null

Returns a public path to **path**, which takes into account the base path set for the package and the URL path. More information in Linking to Assets. Symfony provides various cache busting implementations via the `version`, `version_strategy`, and `json_manifest_path` configuration options.

## asset\_version

*Listing 94-5* 1 `{{ asset_version(packageName = null) }}`

**packageName** (*optional*)  
**type:** string | null **default:** null

Returns the current version of the package, more information in Linking to Assets.

## form

*Listing 94-6* 1 `{{ form(view, variables = []) }}`

**view**  
**type:** FormView

**variables** (*optional*)  
**type:** array **default:** []

Renders the HTML of a complete form, more information in the Twig Form reference.

## form\_start

*Listing 94-7* 1 `{{ form_start(view, variables = []) }}`

**view**  
**type:** FormView

**variables** (*optional*)  
**type:** array **default:** []

Renders the HTML start tag of a form, more information in the Twig Form reference.

## form\_end

*Listing 94-8* 1 `{{ form_end(view, variables = []) }}`

**view**  
**type:** FormView

**variables** (*optional*)  
**type:** array **default:** []

Renders the HTML end tag of a form together with all fields that have not been rendered yet, more information in the Twig Form reference.

## form\_widget

```
Listing 94-9 1 {{ form_widget(view, variables = []) }}
```

**view**

**type:** FormView

**variables (optional)**

**type:** array **default:** []

Renders a complete form or a specific HTML widget of a field, more information in the Twig Form reference.

## form\_errors

```
Listing 94-10 1 {{ form_errors(view) }}
```

**view**

**type:** FormView

Renders any errors for the given field or the global errors, more information in the Twig Form reference.

## form\_label

```
Listing 94-11 1 {{ form_label(view, label = null, variables = []) }}
```

**view**

**type:** FormView

**label (optional)**

**type:** string **default:** null

**variables (optional)**

**type:** array **default:** []

Renders the label for the given field, more information in the Twig Form reference.

## form\_row

```
Listing 94-12 1 {{ form_row(view, variables = []) }}
```

**view**

**type:** FormView

**variables (optional)**

**type:** array **default:** []

Renders the row (the field's label, errors and widget) of the given field, more information in the Twig Form reference.

## form\_rest

```
Listing 94-13 1 {{ form_rest(view, variables = []) }}
```

**view**

**type:** FormView

**variables (optional)**

**type:** array **default:** []

Renders all fields that have not yet been rendered, more information in the Twig Form reference.

## csrf\_token

```
Listing 94-14 1 {{ csrf_token(intention) }}
```

**intention**

**type:** string

Renders a CSRF token. Use this function if you want CSRF protection without creating a form.

## is\_granted

```
Listing 94-15 1 {{ is_granted(role, object = null, field = null) }}
```

**role**

**type:** string

**object (optional)**

**type:** object

**field (optional)**

**type:** string

Returns **true** if the current user has the required role. Optionally, an object can be passed to be used by the voter. More information can be found in Access Control in Templates.

## logout\_path

```
Listing 94-16 1 {{ logout_path(key = null) }}
```

**key (optional)**

**type:** string

Generates a relative logout URL for the given firewall. If no key is provided, the URL is generated for the current firewall the user is logged into.

## logout\_url

```
Listing 94-17 1 {{ logout_url(key = null) }}
```

**key (optional)**

**type:** string

Equal to the `logout_path` function, but it'll generate an absolute URL instead of a relative one.

## path

```
Listing 94-18 1 {{ path(name, parameters = [], relative = false) }}
```

**name**

**type:** string

**parameters (optional)**

**type:** array **default:** []

**relative (optional)**

**type:** boolean **default:** false

Returns the relative URL (without the scheme and host) for the given route. If **relative** is enabled, it'll create a path relative to the current path. More information in [Linking to Pages](#).

*Read [Routing](#) to learn more about the Routing component.*

## url

```
Listing 94-19 1 {{ url(name, parameters = [], schemeRelative = false) }}
```

**name**

**type:** string

**parameters (optional)**

**type:** array **default:** []

**schemeRelative (optional)**

**type:** boolean **default:** false

Returns the absolute URL (with scheme and host) for the given route. If **schemeRelative** is enabled, it'll create a scheme-relative URL. More information in [Linking to Pages](#).

*Read [Routing](#) to learn more about the Routing component.*

## absolute\_url

```
Listing 94-20 1 {{ absolute_url(path) }}
```

**path**

**type:** string

Returns the absolute URL from the passed relative path. For example, assume you're on the following page in your app: `http://example.com/products/hover-board`.

```
Listing 94-21 1 {{ absolute_url('/human.txt') }}  
2 {# http://example.com/human.txt #}  
3  
4 {{ absolute_url('products_icon.png') }}  
5 {# http://example.com/products/products_icon.png #}
```

## relative\_path

```
Listing 94-22 1 {{ relative_path(path) }}
```

**path**

**type:** string

Returns the relative path from the passed absolute URL. For example, assume you're on the following page in your app: `http://example.com/products/hover-board`.

```
Listing 94-23 1 {{ relative_path('http://example.com/human.txt') }}
2   {# ../human.txt #}
3
4   {{ relative_path('http://example.com/products/products_icon.png') }}
5   {# products_icon.png #}
```

## expression

Creates an *Expression*<sup>5</sup> in Twig. See "Template Expressions".

## Filters

### humanize

```
Listing 94-24 1 {{ text|humanize }}
```

**text**

**type:** string

Makes a technical name human readable (i.e. replaces underscores by spaces or transforms camelCase text like `helloWorld` to `hello world` and then capitalizes the string).

### trans

```
Listing 94-25 1 {{ message|trans(arguments = [], domain = null, locale = null) }}
```

**message**

**type:** string

**arguments (optional)**

**type:** array **default:** []

**domain (optional)**

**type:** string **default:** null

**locale (optional)**

**type:** string **default:** null

Translates the text into the current language. More information in Translation Filters.

---

5. <https://api.symfony.com/4.0/Symfony/Component/ExpressionLanguage/Expression.html>

## transchoice

Listing 94-26 1 `{{ message|transchoice(count, arguments = [], domain = null, locale = null) }}`

```
message
  type: string

count
  type: integer

arguments (optional)
  type: array default: []

domain (optional)
  type: string default: null

locale (optional)
  type: string default: null
```

Translates the text with pluralization support. More information in Translation Filters.

## yaml\_encode

Listing 94-27 1 `{{ input|yaml_encode(inline = 0, dumpObjects = false) }}`

```
input
  type: mixed

inline (optional)
  type: integer default: 0

dumpObjects (optional)
  type: boolean default: false
```

Transforms the input into YAML syntax. See Writing YAML Files for more information.

## yaml\_dump

Listing 94-28 1 `{{ value|yaml_dump(inline = 0, dumpObjects = false) }}`

```
value
  type: mixed

inline (optional)
  type: integer default: 0

dumpObjects (optional)
  type: boolean default: false
```

Does the same as `yaml_encode()`<sup>6</sup>, but includes the type in the output.

---

6. [#reference-yaml\\_encode](#)

## abbr\_class

Listing 94-29 1 `{{ class|abbr_class }}`

**class**  
**type:** string

Generates an `<abbr>` element with the short name of a PHP class (the FQCN will be shown in a tooltip when a user hovers over the element).

## abbr\_method

Listing 94-30 1 `{{ method|abbr_method }}`

**method**  
**type:** string

Generates an `<abbr>` element using the `FQCN::method()` syntax. If `method` is `Closure`, `Closure` will be used instead and if `method` doesn't have a class name, it's shown as a function (`method()`).

## format\_args

Listing 94-31 1 `{{ args|format_args }}`

**args**  
**type:** array

Generates a string with the arguments and their types (within `<em>` elements).

## format\_args\_as\_text

Listing 94-32 1 `{{ args|format_args_as_text }}`

**args**  
**type:** array

Equal to the `format_args` filter, but without using HTML tags.

## file\_excerpt

Listing 94-33 1 `{{ file|file_excerpt(line, srcContext = 3) }}`

**file**  
**type:** string

**line**  
**type:** integer

**srcContext (optional)**  
**type:** integer

Generates an excerpt of a code file around the given **line** number. The **srcContext** argument defines the total number of lines to display around the given line number (use **-1** to display the whole file).

## format\_file

```
Listing 94-34 1 {{ file|format_file(line, text = null) }}
```

**file**

**type:** string

**line**

**type:** integer

**text (optional)**

**type:** string **default:** null

Generates the file path inside an `<a>` element. If the path is inside the kernel root directory, the kernel root directory path is replaced by `kernel.root_dir` (showing the full path in a tooltip on hover).

## format\_file\_from\_text

```
Listing 94-35 1 {{ text|format_file_from_text }}
```

**text**

**type:** string

Uses `format_file` to improve the output of default PHP errors.

## file\_link

```
Listing 94-36 1 {{ file|file_link(line) }}
```

**file**

**type:** string

**line**

**type:** integer

Generates a link to the provided file and line number using a preconfigured scheme.

# Tags

## form\_theme

```
Listing 94-37 1 {% form_theme form resources %}
```

**form**

**type:** FormView

**resources**

**type:** array | string

Sets the resources to override the form theme for the given form view instance. You can use `_self` as resources to set it to the current resource. More information in *How to Customize Form Rendering*.

## trans

```
Listing 94-38 1 {% trans with vars from domain into locale %}{% endtrans %}
```

**vars** (*optional*)

**type:** array **default:** []

**domain** (*optional*)

**type:** string **default:** string

**locale** (*optional*)

**type:** string **default:** string

Renders the translation of the content. More information in *Twig Templates*.

## transchoice

```
Listing 94-39 1 {% transchoice count with vars from domain into locale %}{% endtranschoice %}
```

**count**

**type:** integer

**vars** (*optional*)

**type:** array **default:** []

**domain** (*optional*)

**type:** string **default:** null

**locale** (*optional*)

**type:** string **default:** null

Renders the translation of the content with pluralization support, more information in *Twig Templates*.

## trans\_default\_domain

```
Listing 94-40 1 {% trans_default_domain domain %}
```

**domain**

**type:** string

This will set the default domain in the current template.

## stopwatch

```
Listing 94-41 1 {% stopwatch 'name' %}...{% endstopwatch %}
```

This will time the run time of the code inside it and put that on the timeline of the *WebProfilerBundle*.

# Tests

## selectedchoice

Listing 94-42 1 `{% if choice is selectedchoice(selectedValue) %}`

**choice**

**type:** ChoiceView

**selectedValue**

**type:** string

Checks if **selectedValue** was checked for the provided choice field. Using this test is the most effective way.

# Global Variables

## app

The **app** variable is available everywhere and gives access to many commonly needed objects and values. It is an instance of *GlobalVariables*<sup>7</sup>.

The available attributes are:

- `app.user`, a PHP object representing the current user;
- `app.request`, a *Request*<sup>8</sup> object;
- `app.session`, a *Session*<sup>9</sup> object;
- `app.environment`, a string with the name of the execution environment;
- `app.debug`, a boolean telling whether the debug mode is enabled in the app;
- `app.token`, a *TokenInterface*<sup>10</sup> object representing the security token
- `app.flashes`, returns flash messages from the session

## Chapter 95

# Built-in Symfony Service Tags

*Service tags* are the mechanism used by the *DependencyInjection* component to flag services that require special processing, like console commands or Twig extensions.

These are the most common tags provided by Symfony components, but in your application there could be more tags available provided by third-party bundles:

Tag Name	Usage
auto_alias	Define aliases based on the value of container parameters
console.command	Add a command
controller.argument_value_resolver	Register a value resolver for controller arguments such as Request
data_collector	Create a class that collects custom data for the profiler
doctrine.event_listener	Add a Doctrine event listener
doctrine.event_subscriber	Add a Doctrine event subscriber
form.type	Create a custom form field type
form.type_extension	Create a custom "form extension"
form.type_guesser	Add your own logic for "form type guessing"
kernel.cache_clearer	Register your service to be called during the cache clearing process
kernel.cache_warmer	Register your service to be called during the cache warming process
kernel.event_listener	Listen to different events/hooks in Symfony
kernel.event_subscriber	To subscribe to a set of different events/hooks in Symfony
kernel.fragment_renderer	Add new HTTP content rendering strategies
monolog.logger	Logging with a custom logging channel
monolog.processor	Add a custom processor for logging

Tag Name	Usage
routing.loader	Register a custom service that loads routes
routing.expression_language_provider	Register a provider for expression language functions in routing
security.expression_language_provider	Register a provider for expression language functions in security
security.voter	Add a custom voter to Symfony's authorization logic
security.remember_me_aware	To allow remember me authentication
serializer.encoder	Register a new encoder in the <code>serializer</code> service
serializer.normalizer	Register a new normalizer in the <code>serializer</code> service
swiftmailer.default.plugin	Register a custom SwiftMailer Plugin
templating.helper	Make your service available in PHP templates
translation.loader	Register a custom service that loads translations
translation.extractor	Register a custom service that extracts translation messages from a file
translation.dumper	Register a custom service that dumps translation messages
twig.extension	Register a custom Twig Extension
twig.loader	Register a custom service that loads Twig templates
validator.constraint_validator	Create your own custom validation constraint
validator.initializer	Register a service that initializes objects before validation

## auto\_alias

**Purpose:** Define aliases based on the value of container parameters

Consider the following configuration that defines three different but related services:

Listing 95-1

```

1 services:
2   app.mysql_lock:
3     class: App\Lock\MysqlLock
4     public: false
5   app.postgresql_lock:
6     class: App\Lock\PostgresqlLock
7     public: false
8   app.sqlite_lock:
9     class: App\Lock\SqliteLock
10    public: false

```

Instead of dealing with these three services, your application needs a generic `app.lock` service that will be an alias to one of these services, depending on some configuration. Thanks to the `auto_alias` option, you can automatically create that alias based on the value of a configuration parameter.

Considering that a configuration parameter called `database_type` exists. Then, the generic `app.lock` service can be defined as follows:

Listing 95-2

```

1 services:
2   app.mysql_lock:
3     # ...
4   app.postgresql_lock:

```

```

5     # ...
6     app.sqlite_lock:
7     # ...
8     app.lock:
9         tags:
10            - { name: auto_alias, format: "app.%database_type%_lock" }

```

The **format** option defines the expression used to construct the name of the service to alias. This expression can use any container parameter (as usual, wrapping their names with % characters).

When using the **auto\_alias** tag, it's not mandatory to define the aliased services as private. However, doing that (like in the above example) makes sense most of the times to prevent accessing those services directly instead of using the generic service alias.

You need to manually add the `Symfony\Component\DependencyInjection\Compiler\AutoAliasServicePass` compiler pass to the container for this feature to work.

## console.command

**Purpose:** Add a command to the application

For details on registering your own commands in the service container, read *How to Define Commands as Services*.

## controller.argument\_value\_resolver

**Purpose:** Register a value resolver for controller arguments such as `Request`

Value resolvers implement the *ArgumentValueResolverInterface*<sup>1</sup> and are used to resolve argument values for controllers as described here: *Extending Action Argument Resolving*.

## data\_collector

**Purpose:** Create a class that collects custom data for the profiler

For details on creating your own custom data collection, read the *How to Create a custom Data Collector* article.

## doctrine.event\_listener

**Purpose:** Add a Doctrine event listener

For details on creating Doctrine event listeners, read the *Doctrine Event Listeners and Subscribers* article.

1. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Controller/ArgumentValueResolverInterface.html>

## doctrine.event\_subscriber

**Purpose:** Add a Doctrine event subscriber

For details on creating Doctrine event subscribers, read the *Doctrine Event Listeners and Subscribers* article.

## form.type

**Purpose:** Create a custom form field type

For details on creating your own custom form type, read the *How to Create a Custom Form Field Type* article.

## form.type\_extension

**Purpose:** Create a custom "form extension"

For details on creating Form type extensions, read the *How to Create a Form Type Extension* article.

## form.type\_guesser

**Purpose:** Add your own logic for "form type guessing"

This tag allows you to add your own logic to the form guessing process. By default, form guessing is done by "guessers" based on the validation metadata and Doctrine metadata (if you're using Doctrine) or Propel metadata (if you're using Propel).

*For information on how to create your own type guesser, see [Creating a custom Type Guesser](#).*

## kernel.cache\_clearer

**Purpose:** Register your service to be called during the cache clearing process

Cache clearing occurs whenever you call `cache:clear` command. If your bundle caches files, you should add custom cache clearer for clearing those files during the cache clearing process.

In order to register your custom cache clearer, first you must create a service class:

```
Listing 95-3 1 // src/Cache/MyClearer.php
2 namespace App\Cache;
3
4 use Symfony\Component\HttpKernel\CacheClearer\CacheClearerInterface;
5
6 class MyClearer implements CacheClearerInterface
7 {
8     public function clear($cacheDirectory)
9     {
10         // clear your cache
11     }
12 }
```

If you're using the default `services.yaml` configuration, your service will be automatically tagged with `kernel.cache_clearer`. But, you can also register it manually:

Listing 95-4

```

1 services:
2     App\Cache\MyClearer:
3         tags: [kernel.cache_clearer]

```

## kernel.cache\_warmer

**Purpose:** Register your service to be called during the cache warming process

Cache warming occurs whenever you run the `cache:warmup` or `cache:clear` command (unless you pass `--no-warmup` to `cache:clear`). It is also run when handling the request, if it wasn't done by one of the commands yet.

The purpose is to initialize any cache that will be needed by the application and prevent the first user from any significant "cache hit" where the cache is generated dynamically.

To register your own cache warmer, first create a service that implements the *CacheWarmerInterface*<sup>2</sup> interface:

Listing 95-5

```

1 // src/Cache/MyCustomWarmer.php
2 namespace App\Cache;
3
4 use Symfony\Component\HttpKernel\CacheWarmer\CacheWarmerInterface;
5
6 class MyCustomWarmer implements CacheWarmerInterface
7 {
8     public function warmUp($cacheDirectory)
9     {
10         // ... do some sort of operations to "warm" your cache
11     }
12
13     public function isOptional()
14     {
15         return true;
16     }
17 }

```

The `isOptional()` method should return true if it's possible to use the application without calling this cache warmer. In Symfony, optional warmers are always executed by default (you can change this by using the `--no-optional-warmers` option when executing the command).

If you're using the default `services.yaml` configuration, your service will be automatically tagged with `kernel.cache_warmer`. But, you can also register it manually:

Listing 95-6

```

1 services:
2     App\Cache\MyCustomWarmer:
3         tags:
4             - { name: kernel.cache_warmer, priority: 0 }

```

The `priority` value is optional and defaults to 0. The higher the priority, the sooner it gets executed.

If your cache warmer fails its execution because of any exception, Symfony won't try to execute it again for the next requests. Therefore, your application and/or bundles should be prepared for when the contents generated by the cache warmer are not available.

2. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/CacheWarmer/CacheWarmerInterface.html>

## Core Cache Warmers

Cache Warmer Class Name	Priority
<code>TemplatePathsCacheWarmer</code> <sup>3</sup>	20
<code>RouterCacheWarmer</code> <sup>4</sup>	0
<code>TemplateCacheCacheWarmer</code> <sup>5</sup>	0

## kernel.event\_listener

**Purpose:** To listen to different events/hooks in Symfony

During the execution of a Symfony application, different events are triggered and you can also dispatch custom events. This tag allows you to *hook* your own classes into any of those events.

For a full example of this listener, read the *Events and Event Listeners* article.

## Core Event Listener Reference

For the reference of Event Listeners associated with each kernel event, see the *Symfony Events Reference*.

## kernel.event\_subscriber

**Purpose:** To subscribe to a set of different events/hooks in Symfony

This is an alternative way to create an event listener, and is the recommended way (instead of using `kernel.event_listener`). See *Creating an Event Subscriber*.

## kernel.fragment\_renderer

**Purpose:** Add a new HTTP content rendering strategy

To add a new rendering strategy - in addition to the core strategies like `EsiFragmentRenderer` - create a class that implements *FragmentRendererInterface*<sup>6</sup>, register it as a service, then tag it with `kernel.fragment_renderer`.

## monolog.logger

**Purpose:** To use a custom logging channel with Monolog

Monolog allows you to share its handlers between several logging channels. The logger service uses the channel `app` but you can change the channel when injecting the logger in a service.

Listing 95-7

```
1 services:
2     App\Log\CustomLogger:
3         arguments: ['@logger']
4         tags:
5             - { name: monolog.logger, channel: app }
```

3. <https://api.symfony.com/4.0/Symfony/Bundle/FrameworkBundle/CacheWarmer/TemplatePathsCacheWarmer.html>

4. <https://api.symfony.com/4.0/Symfony/Bundle/FrameworkBundle/CacheWarmer/RouterCacheWarmer.html>

5. <https://api.symfony.com/4.0/Symfony/Bundle/TwigBundle/CacheWarmer/TemplateCacheCacheWarmer.html>

6. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Fragment/FragmentRendererInterface.html>

You can also configure custom channels in the configuration and retrieve the corresponding logger service from the service container directly (see [Configure Additional Channels without Tagged Services](#)).

## monolog.processor

**Purpose:** Add a custom processor for logging

Monolog allows you to add processors in the logger or in the handlers to add extra data in the records. A processor receives the record as an argument and must return it after adding some extra data in the **extra** attribute of the record.

The built-in **IntrospectionProcessor** can be used to add the file, the line, the class and the method where the logger was triggered.

You can add a processor globally:

```
Listing 95-8 1 services:
2     Monolog\Processor\IntrospectionProcessor:
3         tags: [monolog.processor]
```

If your service is not a callable (using `__invoke()`) you can add the **method** attribute in the tag to use a specific method.

You can add also a processor for a specific handler by using the **handler** attribute:

```
Listing 95-9 1 services:
2     Monolog\Processor\IntrospectionProcessor:
3         tags:
4             - { name: monolog.processor, handler: firephp }
```

You can also add a processor for a specific logging channel by using the **channel** attribute. This will register the processor only for the **security** logging channel used in the Security component:

```
Listing 95-10 1 services:
2     Monolog\Processor\IntrospectionProcessor:
3         tags:
4             - { name: monolog.processor, channel: security }
```

You cannot use both the **handler** and **channel** attributes for the same tag as handlers are shared between all channels.

## routing.loader

**Purpose:** Register a custom service that loads routes

To enable a custom routing loader, add it as a regular service in one of your configuration and tag it with **routing.loader**:

```
Listing 95-11 1 services:
2     App\Routing\CustomLoader:
3         tags: [routing.loader]
```

For more information, see *How to Create a custom Route Loader*.

## routing.expression\_language\_provider

**Purpose:** Register a provider for expression language functions in routing

This tag is used to automatically register expression function providers for the routing expression component. Using these providers, you can add custom functions to the routing expression language.

## security.expression\_language\_provider

**Purpose:** Register a provider for expression language functions in security

This tag is used to automatically register expression function providers for the security expression component. Using these providers, you can add custom functions to the security expression language.

## security.remember\_me\_aware

**Purpose:** To allow remember me authentication

This tag is used internally to allow remember-me authentication to work. If you have a custom authentication method where a user can be remember-me authenticated, then you may need to use this tag.

If your custom authentication factory extends *AbstractFactory*<sup>7</sup> and your custom authentication listener extends *AbstractAuthenticationListener*<sup>8</sup>, then your custom authentication listener will automatically have this tagged applied and it will function automatically.

## security.voter

**Purpose:** To add a custom voter to Symfony's authorization logic

When you call `isGranted()` on Symfony's authorization checker, a system of "voters" is used behind the scenes to determine if the user should have access. The `security.voter` tag allows you to add your own custom voter to that system.

For more information, read the *How to Use Voters to Check User Permissions* article.

## serializer.encoder

**Purpose:** Register a new encoder in the `serializer` service

The class that's tagged should implement the *EncoderInterface*<sup>9</sup> and *DecoderInterface*<sup>10</sup>.

For more details, see *How to Use the Serializer*.

---

7. <https://api.symfony.com/4.0/Symfony/Bundle/SecurityBundle/DependencyInjection/Security/Factory/AbstractFactory.html>

8. <https://api.symfony.com/4.0/Symfony/Component/Security/Http/Firewall/AbstractAuthenticationListener.html>

9. <https://api.symfony.com/4.0/Symfony/Component/Serializer/Encoder/EncoderInterface.html>

10. <https://api.symfony.com/4.0/Symfony/Component/Serializer/Encoder/DecoderInterface.html>

## serializer.normalizer

**Purpose:** Register a new normalizer in the Serializer service

The class that's tagged should implement the *NormalizerInterface*<sup>11</sup> and *DenormalizerInterface*<sup>12</sup>.

For more details, see *How to Use the Serializer*.

The priorities of the default normalizers can be found in the *registerSerializerConfiguration()*<sup>13</sup> method.

## swiftmailer.default.plugin

**Purpose:** Register a custom SwiftMailer Plugin

If you're using a custom SwiftMailer plugin (or want to create one), you can register it with SwiftMailer by creating a service for your plugin and tagging it with `swiftmailer.default.plugin` (it has no options).

`default` in this tag is the name of the mailer. If you have multiple mailers configured or have changed the default mailer name for some reason, you should change it to the name of your mailer in order to use this tag.

A SwiftMailer plugin must implement the `Swift_Events_EventListener` interface. For more information on plugins, see *SwiftMailer's Plugin Documentation*<sup>14</sup>.

Several SwiftMailer plugins are core to Symfony and can be activated via different configuration. For details, see *SwiftmailerBundle Configuration* ("swiftmailer").

## templating.helper

**Purpose:** Make your service available in PHP templates

To enable a custom template helper, add it as a regular service in one of your configuration, tag it with `templating.helper` and define an `alias` attribute (the helper will be accessible via this alias in the templates):

```
Listing 95-12 1 services:
                2     App\Templating\AppHelper:
                3         tags:
                4             - { name: templating.helper, alias: alias_name }
```

## translation.loader

**Purpose:** To register a custom service that loads translations

---

11. <https://api.symfony.com/4.0/Symfony/Component/Serializer/Normalizer/NormalizerInterface.html>

12. <https://api.symfony.com/4.0/Symfony/Component/Serializer/Normalizer/DenormalizerInterface.html>

13. [https://api.symfony.com/4.0/Symfony/Bundle/FrameworkBundle/DependencyInjection/FrameworkExtension.html#method\\_registerSerializerConfiguration](https://api.symfony.com/4.0/Symfony/Bundle/FrameworkBundle/DependencyInjection/FrameworkExtension.html#method_registerSerializerConfiguration)

14. <http://swiftmailer.org/docs/plugins.html>

By default, translations are loaded from the filesystem in a variety of different formats (YAML, XLIFF, PHP, etc).

*Learn how to load custom formats in the components section.*

Now, register your loader as a service and tag it with `translation.loader`:

```
Listing 95-13 1 services:
                2     App\Translation\MyCustomLoader:
                3         tags:
                4             - { name: translation.loader, alias: bin }
```

The `alias` option is required and very important: it defines the file "suffix" that will be used for the resource files that use this loader. For example, suppose you have some custom `bin` format that you need to load. If you have a `bin` file that contains French translations for the `messages` domain, then you might have a file `translations/messages.fr.bin`.

When Symfony tries to load the `bin` file, it passes the path to your custom loader as the `$resource` argument. You can then perform any logic you need on that file in order to load your translations.

If you're loading translations from a database, you'll still need a resource file, but it might either be blank or contain a little bit of information about loading those resources from the database. The file is key to trigger the `load()` method on your custom loader.

## translation.extractor

**Purpose:** To register a custom service that extracts messages from a file

When executing the `translation:update` command, it uses extractors to extract translation messages from a file. By default, the Symfony Framework has a `TwigExtractor`<sup>15</sup> and a `PhpExtractor`<sup>16</sup>, which help to find and extract translation keys from Twig templates and PHP files.

You can create your own extractor by creating a class that implements `ExtractorInterface`<sup>17</sup> and tagging the service with `translation.extractor`. The tag has one required option: `alias`, which defines the name of the extractor:

```
Listing 95-14 1 // src/Acme/DemoBundle/Translation/FooExtractor.php
                2 namespace Acme\DemoBundle\Translation;
                3
                4 use Symfony\Component\Translation\Extractor\ExtractorInterface;
                5 use Symfony\Component\Translation\MessageCatalogue;
                6
                7 class FooExtractor implements ExtractorInterface
                8 {
                9     protected $prefix;
                10
                11     /**
                12      * Extracts translation messages from a template directory to the catalogue.
                13      */
                14     public function extract($directory, MessageCatalogue $catalogue)
                15     {
                16         // ...
                17     }
                18
                19     /**
                20      * Sets the prefix that should be used for new found messages.
                21      */
```

---

15. <https://api.symfony.com/4.0/Symfony/Bridge/Twig/Translation/TwigExtractor.html>

16. <https://api.symfony.com/4.0/Symfony/Bundle/FrameworkBundle/Translation/PhpExtractor.html>

17. <https://api.symfony.com/4.0/Symfony/Component/Translation/Extractor/ExtractorInterface.html>

```

22     public function setPrefix($prefix)
23     {
24         $this->prefix = $prefix;
25     }
26 }

```

Listing 95-15

```

1  services:
2      App\Translation\CustomExtractor:
3          tags:
4              - { name: translation.extractor, alias: foo }

```

## translation.dumper

**Purpose:** To register a custom service that dumps messages to a file

After a translation extractor has extracted all messages from the templates, the dumpers are executed to dump the messages to a translation file in a specific format.

Symfony already comes with many dumpers:

- [CsvFileDumper](#)<sup>18</sup>
- [IcuResFileDumper](#)<sup>19</sup>
- [IniFileDumper](#)<sup>20</sup>
- [MoFileDumper](#)<sup>21</sup>
- [PoFileDumper](#)<sup>22</sup>
- [QtFileDumper](#)<sup>23</sup>
- [XliffFileDumper](#)<sup>24</sup>
- [YamlFileDumper](#)<sup>25</sup>

You can create your own dumper by extending [FileDumper](#)<sup>26</sup> or implementing [DumperInterface](#)<sup>27</sup> and tagging the service with `translation.dumper`. The tag has one option: `alias`. This is the name that's used to determine which dumper should be used.

Listing 95-16

```

1  services:
2      App\Translation\JsonFileDumper:
3          tags:
4              - { name: translation.dumper, alias: json }

```

*Learn how to dump to custom formats in the components section.*

## twig.extension

**Purpose:** To register a custom Twig Extension

To enable a Twig extension, add it as a regular service in one of your configuration and tag it with `twig.extension`. If you're using the default `services.yaml` configuration, the service is auto-registered and auto-tagged. But, you can also register it manually:

- 
- 18. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/CsvFileDumper.html>
  - 19. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/IcuResFileDumper.html>
  - 20. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/IniFileDumper.html>
  - 21. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/MoFileDumper.html>
  - 22. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/PoFileDumper.html>
  - 23. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/QtFileDumper.html>
  - 24. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/XliffFileDumper.html>
  - 25. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/YamlFileDumper.html>
  - 26. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/FileDumper.html>
  - 27. <https://api.symfony.com/4.0/Symfony/Component/Translation/Dumper/DumperInterface.html>

```
Listing 95-17 1 services:
                2     App\Twig\AppExtension:
                3         tags: [twig.extension]
```

For information on how to create the actual Twig Extension class, see *Twig's documentation*<sup>28</sup> on the topic or read the *How to Write a custom Twig Extension* article.

Before writing your own extensions, have a look at the *Twig official extension repository*<sup>29</sup> which already includes several useful extensions. For example **Intl** and its **localizeddate** filter that formats a date according to user's locale. These official Twig extensions also have to be added as regular services:

```
Listing 95-18 1 services:
                2     Twig\Extensions\IntlExtension:
                3         tags: [twig.extension]
```

## twig.loader

**Purpose:** Register a custom service that loads Twig templates

By default, Symfony uses only one *Twig Loader*<sup>30</sup> - *FilesystemLoader*<sup>31</sup>. If you need to load Twig templates from another resource, you can create a service for the new loader and tag it with **twig.loader**.

If you use the default services.yaml configuration, the service will be automatically tagged thanks to autoconfiguration. But, you can also register it manually:

```
Listing 95-19 1 services:
                2     App\Twig\CustomLoader:
                3         tags:
                4             - { name: twig.loader, priority: 0 }
```

The **priority** value is optional and defaults to **0**. The higher priority loaders are tried first.

## validator.constraint\_validator

**Purpose:** Create your own custom validation constraint

This tag allows you to create and register your own custom validation constraint. For more information, read the *How to Create a custom Validation Constraint* article.

## validator.initializer

**Purpose:** Register a service that initializes objects before validation

This tag provides a very uncommon piece of functionality that allows you to perform some sort of action on an object right before it's validated. For example, it's used by Doctrine to query for all of the lazily-

loaded data on an object before it's validated. Without this, some data on a Doctrine entity would appear to be "missing" when validated, even though this is not really the case.

If you do need to use this tag, just make a new class that implements the *ObjectInitializerInterface*<sup>32</sup> interface. Then, tag it with the `validator.initializer` tag (it has no options).

For an example, see the `DoctrineInitializer` class inside the Doctrine Bridge.

---

## Chapter 96

# Built-in Symfony Events

During the handling of an HTTP request, the Symfony framework (or any application using the *HttpKernel component*) dispatches some *events* which you can use to modify how the request is handled.

## Kernel Events

Each event dispatched by the `HttpKernel` component is a subclass of *KernelEvent*<sup>1</sup>, which provides the following information:

*getRequestType()*<sup>2</sup>

Returns the *type* of the request (`HttpKernelInterface::MASTER_REQUEST` or `HttpKernelInterface::SUB_REQUEST`).

*getKernel()*<sup>3</sup>

Returns the Kernel handling the request.

*getRequest()*<sup>4</sup>

Returns the current Request being handled.

## kernel.request

**Event Class:** *GetResponseEvent*<sup>5</sup>

This event is dispatched very early in Symfony, before the controller is determined. It's useful to add information to the Request or return a Response early to stop the handling of the request.

*Read more on the kernel.request event.*

Execute this command to find out which listeners are registered for this event and their priorities:

Listing 96-1 `$ php bin/console debug:event-dispatcher kernel.request`

  2. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method\\_getRequestType](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method_getRequestType)
  3. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method\\_getKernel](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method_getKernel)
  4. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method\\_getRequest](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/KernelEvent.html#method_getRequest)
  5. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/GetResponseEvent.html>

## kernel.controller

### Event Class: *FilterControllerEvent*<sup>6</sup>

This event is dispatched after the controller to be executed has been resolved but before executing it. It's useful to initialize things later needed by the controller, such as *param converters*<sup>7</sup>, and even to change the controller entirely:

```
Listing 96-2 1 use Symfony\Component\HttpKernel\Event\FilterControllerEvent;
2
3 public function onKernelController(FilterControllerEvent $event)
4 {
5     // ...
6
7     // the controller can be changed to any PHP callable
8     $event->setController($myCustomController);
9 }
```

Read more on the *kernel.controller* event.

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-3 1 $ php bin/console debug:event-dispatcher kernel.controller
```

## kernel.view

### Event Class: *GetResponseForControllerResultEvent*<sup>8</sup>

This event is dispatched after the controller has been executed but *only* if the controller does *not* return a *Response*<sup>9</sup> object. It's useful to transform the returned value (e.g. a string with some HTML contents) into the *Response* object needed by Symfony:

```
Listing 96-4 1 use Symfony\Component\HttpKernel\Event\GetResponseForControllerResultEvent;
2 use Symfony\Component\HttpFoundation\Response;
3
4 public function onKernelView(GetResponseForControllerResultEvent $event)
5 {
6     $value = $event->getControllerResult();
7     $response = new Response();
8
9     // ... somehow customize the Response from the return value
10
11     $event->setResponse($response);
12 }
```

Read more on the *kernel.view* event.

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-5 1 $ php bin/console debug:event-dispatcher kernel.view
```

## kernel.response

### Event Class: *FilterResponseEvent*<sup>10</sup>

---

6. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/FilterControllerEvent.html>

7. <https://symfony.com/doc/master/bundles/SensioFrameworkExtraBundle/annotations/converters.html>

8. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/GetResponseForControllerResultEvent.html>

9. <https://api.symfony.com/4.0/Symfony/Component/HttpFoundation/Response.html>

This event is dispatched after the controller or any `kernel.view` listener returns a `Response` object. It's useful to modify or replace the response before sending it back (e.g. add/modify HTTP headers, add cookies, etc.):

```
Listing 96-6 1 public function onKernelResponse(FilterResponseEvent $event)
2 {
3     $response = $event->getResponse();
4
5     // ... modify the response object
6 }
```

*Read more on the `kernel.response` event.*

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-7 1 $ php bin/console debug:event-dispatcher kernel.response
```

## kernel.finish\_request

**Event Class:** *FinishRequestEvent*<sup>11</sup>

This event is dispatched after a sub request has finished. It's useful to reset the global state of the application (for example, the translator listener resets the translator's locale to the one of the parent request):

```
Listing 96-8 1 public function onKernelFinishRequest(FinishRequestEvent $event)
2 {
3     if (null === $parentRequest = $this->requestStack->getParentRequest()) {
4         return;
5     }
6
7     // reset the locale of the subrequest to the locale of the parent request
8     $this->setLocale($parentRequest);
9 }
```

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-9 1 $ php bin/console debug:event-dispatcher kernel.finish_request
```

## kernel.terminate

**Event Class:** *PostResponseEvent*<sup>12</sup>

This event is dispatched after the response has been sent (after the execution of the *handle()*<sup>13</sup> method). It's useful to perform slow or complex tasks that don't need to be completed to send the response (e.g. sending emails).

*Read more on the `kernel.terminate` event.*

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-10 1 $ php bin/console debug:event-dispatcher kernel.terminate
```

11. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/FinishRequestEvent.html>

12. <https://api.symfony.com/4.0/Symfony/Component/HttpKernel/Event/PostResponseEvent.html>

13. [https://api.symfony.com/4.0/Symfony/Component/HttpKernel/HttpKernel.html#method\\_handle](https://api.symfony.com/4.0/Symfony/Component/HttpKernel/HttpKernel.html#method_handle)

# kernel.exception

## Event Class: *GetResponseForExceptionEvent*<sup>14</sup>

This event is dispatched as soon as an error occurs during the handling of the HTTP request. It's useful to recover from errors or modify the exception details sent as response:

```
Listing 96-11 1 use Symfony\Component\HttpKernel\Event\GetResponseForExceptionEvent;
2 use Symfony\Component\HttpFoundation\Response;
3
4 public function onKernelException(GetResponseForExceptionEvent $event)
5 {
6     $exception = $event->getException();
7     $response = new Response();
8     // setup the Response object based on the caught exception
9     $event->setResponse($response);
10
11    // you can alternatively set a new Exception
12    // $exception = new \Exception('Some special exception');
13    // $event->setException($exception);
14 }
```

The TwigBundle registers an *ExceptionListener*<sup>15</sup> that forwards the **Request** to a given controller defined by the `exception_listener.controller` parameter.

Symfony uses the following logic to determine the HTTP status code of the response:

- If *isClientError()*<sup>16</sup>, *isServerError()*<sup>17</sup> or *isRedirect()*<sup>18</sup> is true, then the status code on your **Response** object is used;
- If the original exception implements *HttpExceptionInterface*<sup>19</sup>, then `getStatusCode()` is called on the exception and used (the headers from `getHeaders()` are also added);
- If both of the above aren't true, then a 500 status code is used.

If you want to overwrite the status code of the exception response, which you should not without a good reason, call `GetResponseForExceptionEvent::allowCustomResponseCode()` first and then set the status code on the response:

```
Listing 96-12 $event->allowCustomResponseCode();
$response = new Response('No Content', 204);
$event->setResponse($response);
```

The status code sent to the client in the above example will be 204. If `$event->allowCustomResponseCode()` is omitted, then the kernel will set an appropriate status code based on the type of exception thrown.

*Read more on the kernel.exception event.*

Execute this command to find out which listeners are registered for this event and their priorities:

```
Listing 96-13 1 $ php bin/console debug:event-dispatcher kernel.exception
```

## Chapter 97

# Requirements for Running Symfony

Symfony 4.0 requires **PHP 7.1.3** or higher to run, in addition to other minor requirements. To make things simple, Symfony provides a tool to quickly check if your system meets all those requirements. Run this command to install the tool:

```
Listing 97-1 1 $ cd your-project/  
            2 $ composer require symfony/requirements-checker
```

Beware that PHP can define a different configuration for the command console and the web server, so you need to check requirements in both environments.

## Checking Requirements for the Web Server

The requirements checker tool creates a file called `check.php` in the `public/` directory of your project. Open that file with your browser to check the requirements.

Once you've fixed all the reported issues, uninstall the requirements checker to avoid leaking internal information about your application to visitors:

```
Listing 97-2 1 $ cd your-project/  
            2 $ composer remove symfony/requirements-checker
```

## Checking Requirements for the Command Console

The requirements checker tool adds a script to your Composer configuration to check the requirements automatically. There's no need to execute any command; if there is any issue, you'll see them in the console output.
